

An Address

ON

THE PATHOLOGY AND TREATMENT OF THE OCULAR COMPLICATIONS OF GONORRHOEAL INFECTION.

Read before the Hunterian Society on Nov. 14th, 1906.

By W. J. MCC. ETTLES, M.D., CH. M. ABERD.,
F.R.C.S. EDIN.,

FELLOW OF THE SOCIETY.

MR. PRESIDENT AND GENTLEMEN.—Before proceeding, let me to express my deep sensibility of the compliment paid by your request that I should undertake the study of ocular manifestations in this general review of our knowledge of gonorrhoeal affections. In order that, within the necessarily brief limits accorded me, I might have sufficient time for the discussion of more modern views on causes and treatment, I have ventured to eliminate references, on the one hand, to such excessively rare conditions as gonorrhoeal pyodermatitis or suppuration of the accessory sinuses of the head, and, on the other hand, to well understood points, such as the clinical evidence of ophthalmia or iritis, as well as the treatment of iritis and corneal ulcer. The points which will be submitted to you are (a) the prophylaxis of ophthalmia neonatorum; (b) the genesis and incubation of gonorrhoeal conjunctivitis and iritis; and (c) the specific treatment of gonorrhoeal conjunctivitis whether attacking the adult or newly born eye.

THE PROPHYLAXIS OF OPHTHALMIA NEONATORUM.

In the history of the campaign against gonococcal invasion signal successes stand out in strong relief. The first the recognition of gonorrhoea as a distinct pathological condition by Ricord in 1831; the second, the discovery of the cococcus by Neisser and Bouchard in 1878; the third, the statement of Koch's postulates by Bumm and later workers; the fourth, the discovery of the influence of silver by Credé in 1880. "Lest we forget" how important that treatment is, let me refer to the statement of Girales:¹ "The loss in the Foundling Hospital of Paris, at a period just before the Franco-German war, was between 80 and 90 per cent. of all births." Years ago it was calculated that there were over 1000 blind people in Europe and from the reports of blind asylums at that time it appeared that "30 to 40 per cent. of the inmates owed their profound misfortune to this, a wholly preventable disease." We must not be led into thinking that its ravages are abating. As Fournier Haab recently remarked, "it is the direct cause of blindness in one-third of all cases, being surpassed in this respect only by small-pox in countries where vaccination is efficiently enforced . . . in spite of the higher standard of hygiene and more competent medical treatment of the present day, the disease defies all efforts to eradicate it on account of the negligence on the part of the persons in attendance not seeking assistance early enough, and because the disease is, and always will be, dangerous in spite of the improved methods of treatment."

The striking value of Credé's method is shown by the results of large maternity charities where it is rigidly enforced. Within the antiseptic period the proportion of ophthalmia neonatorum was about 1 in every 5 cases; immediately after it dropped to about 1 in every 500, at which approximation it remains. Owing mainly to what the newspapers recently termed "our national squeamishness" ophthalmia neonatorum is more prevalent in Great Britain than it is abroad; at any rate, in the German-speaking States. As Dr. E. Herman, a former president of this society, pointed out at a recent discussion at the Obstetrical Society of London, a young practitioner hesitates to employ Credé's drops in any case lest it should be said of him that "he always does something to the baby's eyes which causes them to become inflamed," while it would be impossible for him to justify his action on the ground that gonorrhoeal infection might be present. Popular prejudice is a terrible obstacle to one can sympathise with the difficulty.

Fortunately we now have at our command the organic compounds of silver which have even more prophylactic value than the nitrate without possessing its irritant properties.² In view of the tragic potentialities of the disease their use should surely be compulsory. The cleansing of the eyes should never be delegated to the nurse. A quantity of protargol, which can be very conveniently carried in compressed tablets, is dissolved in boiled and cooled water—it need not be distilled—in sufficient amount to make a fresh 6 per cent. solution. This is poured into the conjunctival sacs and the lids are so separated as to permit the fornices being reached. There is no inflammatory reaction. Collargol is also very well tolerated by the epithelium and so is argyrol, but the last named I have found less active and reliable than either of the former. The whole procedure is a very simple one and we may contrast it with that recently advocated by Stellwag and Wintersteiner,⁴ who irrigate the eyes with a 1 in 1000 solution of permanganate of potassium and daily instil 2 per cent. of nitrate during the whole lying-in period. In justice to them I must explain that their idea is absolutely to stamp out the disease, but the method is too rigorous for universal adoption.

THE GENESIS AND INCUBATION OF GONORRHOEAL CONJUNCTIVITIS AND IRITIS.

Like the urethral affection, we may divide the clinical history of ophthalmia into the several stages of incubation, copious discharge, and ocular gleet. When we compare the incubation period as generally given in text-books we find it is greatly at variance with that of urethritis. Some go so far as to say that the symptoms "usually begin within a few hours after infection:"⁵ whereas in the urethra "it very rarely occurs that the period of incubation is less than two days. Instances recorded as such are generally to be explained as exacerbations of latent chronic gonorrhoea, and not as fresh infections."⁶ The discrepancy is mainly due to the difficulty, often the impossibility, of ascertaining the exact moment of inoculation, at least in adult cases. The rubbing of the lids is an almost unconscious act, while the day and hour of an impure connexion is usually branded on the memory of the sufferer. In point of fact, the actual period has been determined beyond cavil by experimental inoculation. Some years ago it was a legitimate treatment of inveterate trachomatous pannus to inoculate the eye with gonorrhoeal matter, and where that was done the incubation was found to be an invariable period of 60 hours.⁷ It is, however, becoming increasingly clear that we may have a true metastatic or endogenous infection due in some instances to the presence of the organism and in others to that of a toxin. Such cases have recently been described by Swan M. Burnett,⁸ Giani,⁹ and notably by Sidney Stephenson and Rosa Ford.¹⁰ The two last-named collected a remarkable series of cases in which the membranes ruptured within 24 hours of delivery and yet the disease was either present at birth or commenced within 24 hours thereof. In most of their own cases the gonococcus was found, but in some it was absent. Only three weeks ago I had an opportunity of seeing a case, by the courtesy of Dr. W. J. Galt, in which a middle-aged man with antero-posterior urethritis developed a sudden bilateral purulent ophthalmia. No microbes were found in the discharge in spite of the most careful search, whereas myriads were present in the urethral pus. Giani proposes to classify such cases as paragonorrhoeal, in the same sense as Fournier grouped the parasyphilitic lesions. In all cases we find a pre-existing focus of infection from which organisms or toxins can gain entrance to the circulation. In adults it is noteworthy that disease of the posterior urethra is invariably present, while joint affections are commonly associated.

It is in connexion with this probable gonotoxin that I would introduce the question of iritis. Here also we find a well-defined complication, not dependent on the actual presence of the microbe in the lesion, invariably associated with posterior urethritis, and generally with arthroses (Baylac,¹¹ Galezowski,¹² and others). Iritis is, I believe, a

commoner complication than is generally supposed. The presence of gonorrhoeal rheumatism is exceedingly likely to cause its being mistaken for ordinary rheumatic iritis, especially as the patient will seldom volunteer a statement about his urethritis, and, in two misguided cases I have seen, actually denied its presence. In women it is, of course, exceedingly difficult to make sure of the diagnosis.

THE TREATMENT OF GONORRHOEAL CONJUNCTIVITIS.

Taking the ordinary case of an infant, commencing on the third day, we find the usual condition: the upper lid red, glossy, oedematous, overhanging the lower; the lids gummed by dried matter, the scarlet villous palpebral conjunctiva and theropy pus. The microscope may be used to clinch the diagnosis, but it is a matter of scientific rather than therapeutic interest. What we at once look at is the cornea, and as to this we have a rule—almost a canon of surgery—"if the cornea is clear a favourable issue may be predicted." The neonatal cornea is exceedingly vulnerable, the more so as there are no tears to protect it and the affected infants are so often syphilitic. At the best, the cornea is not remarkable for vitality. Dependent for its nutrition on lymph diffusing along the interlamellar canals from the marginal vascular loops, any stasis in the circumcorneal vessels will threaten necrosis. In the infant it is thinner as to the substantia propria and yet more so in the epithelium, where, instead of a transitional layer five or six cells thick, it consists of one layer of squames on a single layer of cuboidal cells. Hence we can understand how it is that whilst in the adult the ulcers are usually peripheral and are caused by the retention of pus between the corneal edge and the overhanging ring of chemosed conjunctiva in the infant the ulcer is central from simple devitalisation. That such stasis exists is clear from the researches of Schridde,¹³ Golesecano,¹⁴ and others.

On the question of remedies, beyond a universal admission of the specific value of silver salts, the atmosphere is almost polemic. For some time nitrate of silver was thrown in the shade by the newer organic preparations, whose universal goodness glowed so enticingly in our daily batch of circulars. But it was not long before it came into its own again and we find Th. Saemisch, in the new edition of Graefe and Saemisch's "*Handbuch für Augenheilkunde*," discarding entirely the new compounds and plugging his faith to the old salt. In this he is supported by many of the foremost authorities, notably by Bernheimer,¹⁵ Baillart,¹⁶ and Alvarado.¹⁷ So far the strongest rival of the nitrate is protargol,¹⁸ and Saemisch's attack elicited a vigorous rejoinder from Pfalz¹⁹ who has used protargol exclusively for six years and never required a solution stronger than 10 per cent.

In my own experience I have learned to rely greatly on protargol much more than on any of the others, but one difficulty—and it is indeed a drawback—is the need for its continuous use in a serious case. Whereas with the nitrate one can manage well with three applications daily, with protargol applications have to be made every half hour, day and night, so that the patient, to say nothing of the attendants, is worn out by want of sleep. Apart from this, it is questionable if it is really equal to the nitrate, as witness the statement of Darier and Abadie,²⁰ that whenever the cornea shows signs of necrosis they always resort to the nitrate. In the adult my practice is, firstly, to irrigate the sound eye and then to instil 10 per cent. protargol before putting on the Buller shield, since we have no ground for assuming its freedom from infection. The affected eye is then irrigated thrice daily with 200 cubic centimetres of a solution of nitrate, 1 in 300, in warm distilled water. After each irrigation, applied by a glass undine, I instil two drops of 2 per cent. nitrate and do not neutralise with salt solution. In all adult cases I divide the external canthus. This may seem a heroic proceeding but in view of the extreme danger to sight it is insignificant. One blade of a pair of strong scissors is pushed under the commissure as far as it will go, and the intervening tissues are severed at a single stroke. The outer tarsal ligament is very resilient and will elude the grasp of any but sharp blades. It is remarkable how greatly this facilitates the proper handling of a

case. The cornea is at once removed from pressure the oedematous lids are depleted by the free blood and orbicular spasm is also done away with. Even a valuable is the free access to the retrotarsal fold. Owing to what one would expect, when all swelling has subsided there is very little wound left and blepharoplasty is needed, although that would be a simple matter if it were. During the interval between the irrigations it is usual to employ frequently renewed dressings kept moist and cold a block of ice. As a general surgical measure, the use of cold topical applications is diminishing as a result of increased acquaintance with the pathology of inflammation. This applies with unusual force to ophthalmic surgery where there is *ab initio* a lessened vitality, in the face of which it is illogical to reduce the corneal temperature, where, moreover, owing to the thinness of the intercorneal tissues, the temperature can be influenced to an unusual degree. Warm applications, on the other hand, maintain impaired nutrition and are much more grateful to patient than cold ones. When the stage of ocular gloeitis has been reached it will be found, as in urethral work, simple astringents are of more use than the antiseptics. There are many which may be employed but I have found none superior to the old-fashioned "*lapis divinus*" put on the inner surfaces of the lids.

ON SUBSTANCES FAVOURING AND INHIBITING THE ACTION OF THE HÆMOLYSINS OF BILE AND SERUM.

By M. ARMAND RUFFER, M.A., M.D. OXON., C.M. AND

M. ORENDIROPOULO.

(From the Port Vicus Laboratory, Alexandria.)

INTRODUCTION.

In the course of some previous investigations it noticed that an animal might have marked jaundice with any obvious alterations in the structure of red corpuscles and that the serum of an animal had a hæmosozic effect on the bile of that species of animals from which the serum been taken. Later, we showed that urine prevented action of certain hæmolytic sera and that this hæmosozic effect could not be due to the presence of salts only dialysed urine had the same effect. The present paper concerned with the influence of various substances (urine, sugars) on the hæmolysis produced by various fluids such as bile, and specific sera.

I. EFFECT OF CONCENTRATION OF SALTS ON BILE METHODS USED.

(a) *Preparation of blood.*—A measured quantity of ox blood was washed with normal (9 per 1000) salt solution and centrifuged. The supernatant liquid was decanted and replaced with fresh normal salt solution, and after process had been repeated three times the washed blood corpuscles were suspended in a quantity of normal salt solution equal to the original volume of fluid. When used washed blood was never more than two or three hours old.

(b) *Preparation of standard solution of bile.*—As the hæmolytic properties of bile vary greatly a solution of apparently constant strength was prepared by suspending a measured volume of bullock's blood (prepared as above) in normal salt solution and ascertaining what amount of normal salt solution dissolved one volume of blood in 10 minutes. If, dissolved the blood completely in ten minutes. If, instance, one volume of bile added to nine volumes of (9 per 1000) salt solution dissolved one volume of blood in 10 minutes, then the standard solution used on that day made up of nine cubic centimetres of normal salt solution plus one volume of bile. If two volumes of bile dissolved one volume of blood, the standard solution for the day contained two cubic centimetres of bile and eight volumes of normal salt solution. Such a standard solution (hereafter called standard bile) was prepared every day. Unless otherwise stated 0.1 cubic centimetre of this standard bile was added to each cubic centimetre of fluid in all our experiments.

(c) *Preparation of mixture of blood and bile.*—1 per cent. 10 per cent., or more concentrated solutions of the salts tested were prepared and varying volumes of these solutions were added in test-tubes to distilled water (in such portions that each tube contained exactly one cubic

Experiments with sodium chloride.—If one drop of blood added to 0·9 cubic centimetre of normal salt solution rather with 0·1 of standard bile no hæmolysis takes place, but if the blood is suspended in the same volume of a tonic solution of the same salt and the same quantity bile the result is quite different. The following table illustrates this:—

NaCl.		Result.	
0.05 per cent. ..	...	...	60

11 " ...	I	I	I	I	I	I	I

A certain volume (0·1 cubic centimetre) of standardised bile, therefore, added to one cubic centimetre of an isotonic or nearly isotonic solution of certain salts (e.g., sulphate of sodium, barium chloride, phosphate of ammonium, nitrate of ammonium, magnesium salts, and chloride calcium) dissolves one drop of blood within half an hour. The same volume of bile mixed with one cubic centimetre of a solution of the other salts (sodium chloride, iodide of potassium, bromide of sodium, nitrate of sodium, chloride of potassium, &c.) dissolves one drop of blood suspended in markedly hypertonic solutions. The activity of bile increases as the solutions become more hypertonic, just as it does in NaCl solutions. The salts of the first group (sulphate of sodium, &c.) also are least active when blood is suspended in isotonic or slightly hypertonic solutions. This can easily be proved by diminishing the quantity of bile. Let us take CaCl₂ as an example.

	Calcium chloride solutions.			
	1%	2%	3%	4%
St. B. 0.1 c.c. ...	I	I	I	I
" 0.05 c.c. .	I	I	I	I
" 0.025 c.c. ...	—	—	—	I

Comparative action of salts.—Certain salts therefore favour the haemolytic properties of bile far more than others. An approximate idea of the favouring properties of each salt is obtained by adding varying volumes of standardised bile to

the on hæmolytic sera is very remarkable and is demonstrated in the following experiment:—

TABLE IX.—The Action of Calcium Chloride on Hæmolytic Sera.

	Serum.	Physiological salt solution.	1% CaCl ₂ solution.	Red blood corpuscles.	Result.
...	0.1	0.3	0.1	1 drop.	+++ (18 h.)
...	"	0.7	0.2	"	+
...	"	0.6	0.3	"	00

As soon as the solution contains 0.03 per cent. of calcium chloride no hæmolysis takes place. This action of calcium chloride on hæmolytic serum, therefore, is exactly the opposite of the action of the same salt on bile and, it may be added incidentally, on some agglutinating sera.

Effect of adding increased quantities of serum to red blood corpuscles suspended in hypertonic salt solutions.—As has been already mentioned, hæmolytic serum (1 per 1000) acting rapidly on blood suspended in a 9 per 1000 solution of sodium chloride does not dissolve blood suspended in a 2 per cent. solution of the same salt. Another series of experiments showed that no hæmolysis takes place as soon as the mixture contained 1.4 per cent. of sodium chloride, even if the volume of serum be increased. If, for instance, instead of 1 per 1000, 1.25 per cent. of serum was added, no hæmolysis took place when the mixture contained 1.4 per cent. of sodium chloride. Even more remarkable is the inhibiting effect of calcium chloride. Whereas a 1 per 1000 solution of a given serum immediately dissolves a given quantity of blood suspended in a 9 per 1000 solution of sodium chloride, a 1 per cent. solution of the same serum is inactive as soon as the mixture contains 1.3 to 0.04 per cent. of calcium chloride.

EFFECT OF URINE ON THE HÆMOLYSIS PRODUCED BY BILE AND SERUM.

From the fact that urine contains a large quantity of salts it was confidently expected that it would have a favouring effect on the hæmolysis produced by bile. The following experiment confirms this view.

TABLE X.—The Effect of Urine on the Hæmolysis produced by Bile and Serum.

	Bile.	Physiological salt solution.	Human urine.	Blood.	Result.
I. (Control)	0.02	1 c.c.	0	1 drop.	+
II. "	"	0.5	0.5	1 "	++
III. "	"	0.4	0.6	1 "	+++
IV. "	"	0.3	0.7	1 "	I
V. "	"	0	1 c.c.	1 "	I

In a further series of experiments half this quantity of the hæmolytic almost completely one drop of blood suspended in human urine, but not the same quantity of blood suspended in physiological salt solution. The favouring effect of urine, however, is not wholly due to the salts contained in it.

Experiment.—50 cubic centimetres of fresh human urine were mixed with 150 cubic centimetres of absolute alcohol and the precipitate was dialysed until all the salts had disappeared. The liquid remaining in the dialyser was precipitated with twice its volume of alcohol. Physiological solution was then added to the precipitate until the total amount of fluid amounted to 25 cubic centimetres. This we shall call D.U.

TABLE XI.—The Effect of Urine Freed from Salts.

	Bile.	Physiological salt solution.	D.U.	Red blood corpuscles.	Result.
I. (Control)	0.2	1 c.c.	0	1 drop.	+
II. "	0	0	1 c.c.	1 "	0
III. "	0.2	0.5	0.5	1 "	I
IV. "	0.2	0	1	1 "	I

Even when half the quantity was added the blood suspended in D.U. was dissolved immediately. Urine, therefore, even when freed from salts exerts a favouring influence on the hæmolysis produced by bile.

Effect of urine on hæmolysis produced by hæmolytic sera.—This question has been fully discussed in our paper published in the *Journal de Pathologie*. Among the conclusions arrived at two are of special interest: First, human urine inhibits the hæmolysis produced by hæmolytic sera prepared by the injection into rabbits of bovine red blood corpuscles; and secondly, this anti-hæmolytic action (or hæmosozic action) is not due to the salts contained in the urine, as dialysed urine is equally effective.

Conclusion.—Human urine favours the hæmolytic action of ox bile but inhibits the hæmolytic action of sera prepared by the injection of bovine red blood corpuscles. In both cases the effect is not wholly due to the presence of salts.

Experiments with various sugars.—If 0.1 of standardised bile be added to different solutions of saccharose, glucose, or lactose, hæmolysis takes place only in highly concentrated solutions of these sugars.

TABLE XII.—The Effect of Sugars on the Hæmolytic Action of Bile.

	Solutions of sugars + St. B. 0.1.												
	3%	4%	5%	6%	7%	8%	9%	10%	20%	30%	40%	50%	
Cane sugar	I	I	+++	++	+	-	-	-	-	-	-	D (5)	
Lactose	I	I	+++	+	-	-	-	+++	-	++	-	-	
Glucose	++	++	-	-	-	-	-	-	-	-	-	D (5)	

Under similar conditions the action of hæmolytic sera is different.

TABLE XIII.—Effect of Sugars on Hæmolytic Action of Sera.

	Solutions of sugars + hæmolytic serum 0.1.																		
	2%	3%	4%	5%	6%	7%	8%	9%	10%	11%	12%	13%	14%	15%	16%	17%	18%	19%	20%
Saccharose	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	-
Glucose	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	-
Lactose	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	C	-

Hæmolytic serum therefore does not act when the solution of sugars is highly concentrated.

Conclusion.—High concentration of sugars favours the action of bile and hinders that of hæmolytic serum.

Alexandria.

THREE STOMACH CASES FROM THE PHYSICIAN'S STANDPOINT: A POST-GRADUATE CLINIC.

BY WILLIAM RUSSELL, M.D., F.R.C.P. EDIN.,

SENIOR ASSISTANT PHYSICIAN, ROYAL INFIRMARY; AND LECTURER ON PRACTICE OF MEDICINE, EDINBURGH.

In some quarters it seems to be thought that the time is not far distant when the art of the physician will become obsolete and be replaced by the craft of the surgeon. If this prediction be ever realised the fault will lie at the door of the physician and of the general practitioner. The latter, however much more he may be, ought certainly to be a physician, for to be a successful practitioner, in the only true sense, requires that he should be a careful and, as far as possible, a skilful diagnostician. In no region has a more debatable land arisen than in the domain of gastric disorder, and the cause of this is to be found in the following considerations.

In the very nature of things digestive and gastric disturbance comes into the hands of the practitioner and the physician. It is on them that the responsibility of diagnosis must primarily lie, and it is imperative that they should rise to their extended responsibilities in this department and

¹ These notes have necessarily been extended to make them suitable for publication.

devote themselves to the attainment of skill in the differential diagnosis of abdominal diseases. That a gastric condition may require a surgical operation no more removes it from the domain of the practitioner and the physician than the diagnosis of an empyema lies with the surgeon because he is called in to operate on it. The contrary idea is but an illustration of what we have recently heard a good deal in other affairs—a want of clear thinking. The physician has above all else, and in the first place, to be a diagnostician; and the position assumed in some quarters that he is not to be allowed to use his art in the disorders and diseases of the abdomen is as amusing as it is astounding. There is no doubt that the opening up of abdominal surgery has made it necessary to be more precise, more definite, more detailed in diagnosis than formerly. We are no longer satisfied with such diagnoses as dyspepsia, hæmatemesis, jaundice, colic, intestinal obstruction, or peritonitis; and the physician ought to be the pioneer in that whole realm of diagnosis. It is on him that the onus lies of indicating the paths and methods of differential diagnosis in the abdomen, as he has done in the thorax and in the brain. He is not justified in abandoning his birth-right in internal diagnosis. Whatever difficulties there may be, or appear to be, they have to be faced and solved. Not only ought he to be a pioneer in differential diagnosis, but he ought to be more, for, however much the surgeon's craft may be requisitioned by him, he ought to know as well as the surgeon not only the diseases which require operation but also the kind of operation that may or can be done in the various diseases with which he has to deal.

Surgery is not an occult science; even such questions as the advantages of anterior or posterior gastro-enterostomy are copiously, not to say openly, discussed. The physician knows, or ought to know, that if he diagnoses certain conditions the treatment is gastro-enterostomy, although he leaves it to the surgeon to select the method of operating; and that, if he diagnoses other conditions, they are not worth meddling with unless they can be removed entirely. Sometimes one gets the impression that the physician thinks he ought not even to know what the surgeon will do in any particular case, which is as curious an affectation as if he professed ignorance of how a broken leg or a dislocated shoulder is treated. If the physician diagnoses gall-stones he knows that the surgeon to remove them has to use the knife; the line of incision and whether catgut or silk be used is no part of his responsibility, but it is absurd to affect ignorance of, or want of intelligent appreciation of, the dexterity and skill of the surgeon in carrying out all the details of the operation and the after-healing of the wound. If the physician is confident of his diagnosis he will not usually have any serious difficulty in convincing his surgical confrères that operation is desirable. Difficulty arises more frequently, perhaps, when the surgeon recommends an "exploratory" operation and the physician does not agree with him. The "exploratory" operation tends, indeed, to be so widely applied and advocated that it threatens to be the bane of differential diagnosis. It has its own place, but when it becomes the screen for careless, ill-informed opinion, or for ignorance of methods, it would be difficult to apply too damnatory criticism to it.

If the physician's first duty is diagnosis, his second is to know enough of surgical methods and of surgical successes to understand and appreciate what he recommends his patient to submit to. These are essential for the physician whether he be a family practitioner or a hospital consultant, for to him will assuredly come the vast majority of abdominal cases. The responsibility is laid upon him of making accurate and detailed diagnoses. There is really little difference of opinion as to what treatment ought to be pursued in definite conditions; the whole difficulty lies in a weak diagnosis. In abdominal disease and disorder there has been a sudden new demand upon the physician's skill, and there seems sometimes to be a tendency or a desire to shirk the new responsibility. This is, no doubt, largely due to the idea that as abdominal diagnosis was vague in the past it must remain so, and the champions of "exploratory" operation do nothing directly to remove this idea.

It seems to me that not only for the sake of the physician's reputation, but also for the maintenance of public confidence in surgery, every effort ought to be made to secure increasing accuracy in abdominal diagnosis—that is, in the differentiation of conditions which present a certain surface-resemblance to one another. The responsibility for such advance lies chiefly with the hospital physician, for it is he who has the

done "exploratory" operations will be undertaken more enlightened principles than seem at present vogue. The practitioner and the physician will that the diagnosis of certain conditions imperatively the recommendation of surgical operation. It is mainly a question of whether to operate or accuracy and completeness of diagnosis. "operation is really an acknowledgment of failure, only by regarding it in this light that advance can

I am to show you, in the short time at our disposal, stomach cases, indicating the points in each case on base the diagnosis. They are all cases which, in my ought to be operated on, and I hope to be able so that you will have the opportunity of operations.

CASE 1. *Pyloric narrowing; gastric dilatation*. The patient, a married man, aged 34 years, was the Edinburgh Royal Infirmary on August 29th. He complained of vomiting, of pain in the abdomen and that he had been very bad for the preceding six going into his history it was ascertained that he troubled with his stomach for 15 years—that is, since a youth of 19 years. The general description of ptosis was that he had discomfort, fullness, and in the stomach, coming on usually about an hour. The discomfort was sometimes followed by, and with vomiting. Sometimes the vomiting was at night. vomit when copious, he thought, consisted of what taken for some days. The vomit had sometimes in colour and frothy. 12 years ago he was the infirmary for dilated stomach and for the dition two years later. Since that time he had been off and on with his stomach. During the past year had comparatively little trouble until six weeks admission, when discomfort, pain, and vomiting. The discomfort and vomiting became very severe and, confident, worse than ever before experienced. He flesh and, of course, weight. Constipation had been the bowels only moving once a week if left to. There was no history of melæna or of vomiting. poured out blood. The patient had a fresh complexion very lean.

Such are the essential points in the history of this ailment. Let me show you how the boundaries stomach can be determined without artificially. a method I have not found it necessary to adopt. stomach has not been emptied for 24 hours, so if a favourable condition for our present purpose. If the are placed, as I place my hands, on this patient's body, use them so as to produce a succussion wave in the contents, and by means of this wave I determine the of the lower border of the viscus—it is below the level of the umbilicus at present. You may be able by this method trace the greater curve of the stomach upwards, and the left lower border of the thorax. Then, as regards the position of the fundus you can often find it by percussion—by finding the point at which tympanicity begins. At particular moment this is not available in this, as the stomach is so full, but if you reverse the succussion wave you can feel it quite easily, and that it goes as high as the fifth rib and may even higher. By percussion and succussion I can also determine the position of the lesser curvature in the epigastrium. can thus outline the stomach to you on the surface of the thorax and abdomen. Try this yourselves; the method requires a little practice and it is absolutely reliable. difficulty is made in abdominal diagnosis by all kinds of strange imaginings. The succussion wave here is produced in the stomach and cannot be anywhere else; and, much you may marvel at the size of the organ the outline is absolutely correct. I remove the stomach contents so you may see their character and quantity and we can show you that they contain free hydrochloric acid and can estimate rapidly the total acidity and the amount of hydrochloric acid present.

Remarks.—This is an example of gastric disorder of duration, which came on early in life, and at the comparatively early age of 34 years has made activity impossible. Although the earlier symptoms of disorder cannot be recalled with certainty there are indications that the type was hyperacidity. 12 years ago he was treated for stomach dilatation, but the name applied to the condition at that time, not really help us, for dilatation may be due to a considerable variety of causes, from malignant pyloric stricture

7. That the dilatation cannot have been due to stricture at the pylorus, or, indeed, to permanent any cause, is indicated by the history of freedom from symptoms, one of which periods last 12 months up to six weeks ago.

recurring dilatation are, in my experience, most hyperchlorhydria. The sequence of events is an attack of hyperchlorhydria comes on from one of several causes, and, unless successfully goes on to a moderate measure of dilatation; ie hyperacidity exists so long does the tendency remain; and when the two co-exist the dilatation increases and may become very great. In this case, on more than one occasion, have been great or the patient gives a history of vomiting large of frothy material. During the six weeks of the case there has been very copious emesis, but the patient has not been frothy. He must have recovered serious attacks of great dilatation, for if he had not possibly have had the freedom from symptoms, as we have seen, he evidently experienced. An attack has apparently been the most severe he is most solicitous to have some radical means relieve it. We are all the more ready to fall in because there has been no improvement in spite of emptying of his stomach by the tube, followed by lavage, and of careful dieting. His stomach in proportion of the substances and fluids introduced, and, as is usual in such cases, pours out fluid in addition to the volume of the gastric contents. The stomach is emptied by vomiting or by the tube. The contents are fluid, of the thickness of cream or gruel. In colour, being drab, dark grey, or brownish.

may contain as much as three pints, that amount vomited, and an equal amount has been withdrawn. The total acidity is high and there is abundant chloric acid. The very important question has arisen in this case, Why is the present attack so severe and not amenable to medical measures taken for its relief?

Of course, no doubt as to the existence of a hindrance at the pylorus; without that there would be such marked retention in the stomach of what it. There is no thickening at the pylorus. The absence of such thickening and the presence of abundant chloric acid are against a diagnosis of malignancy. There has never been hæmatemesis, although the stomach contents have almost certainly owed their colour on many occasions to altered blood. There is no definite history of ulcer of the stomach, such as is usually present in considerable abrasion or a chronic ulcer is. The symptoms are such as accompany hyperchlorhydria, and retention. The particular point of elucidation in the present attack is the amount of food and the failure to remove the condition.

From what I have formed is this: The patient had an severe attack of his recurring hyperchlorhydria, followed by dilatation, the dilatation being greater possibly on other occasions. When there is dilatation the stomach sags, and the greater the dilatation the more sagging tends to become from the mechanical pressure of the contents dragging upon it. After a time the stomach is added to dilatation. With ptosis the stomach is usually more or less dragged down also. In this case I have not been able to determine any lowering of the stomach. An explanation of the hindrance to the outflow of gastric contents can be found by supposing that old adhesions at the pylorus which lead to a stricture at the pylorus when dilatation and ptosis come upon the organ. This would explain the periods of freedom from symptoms; it would explain the difficulty when the stomach is full. With this picture of the case before us we are led to operation with hope and confidence. We shall not only do a gastro-enterostomy but to any such adhesions, as we have referred to, which are present. While saying this you, I hope, realise that I do not doubt as to a mechanical difficulty at the pylorus, but believe neither to be due to recent ulcer nor to disease.

After operation.—Mr. F. M. Caird did a gastro-enterostomy on this patient on Sept. 29th. The pylorus was found up under the liver; the stomach was greatly enlarged. There were no adhesions of the pylorus to any parts, as we thought might be found. The stomach at the pylorus was due to an indurated and

apparently fibroid condition of the pyloric ring. This condition of the pylorus and its high position, along with the dilatation and ptosis of the stomach, were amply sufficient to explain the difficulty at the pylorus. There was no evidence of recent or of chronic ulceration. Some of the glands along the inferior aspect of the pylorus were enlarged, but Mr. Caird, while removing one for examination, did not think they suggested malignancy. The main points in the diagnosis were: (1) pyloric obstruction; (2) not due to recent ulceration; (3) not due to malignant growth; (4) but due to old changes around the pylorus. The first three points were confirmed at the operation, while as regards the fourth instead of pyloric adhesions there was an old fibroid stricture which, along with the high position of the pylorus and the ptosis, caused the difficulty.

CASE 2. Duodenal ulcer.—The patient, a married man, aged 28 years, was admitted to the Edinburgh Royal Infirmary on Sept. 21st, 1906. He complained of pain in the epigastrium, all round that part of the right side corresponding to the hepatic region, and in the back. The symptoms complained of had lasted for four weeks. On inquiring into the history, it was ascertained that he had suffered off and on for five years from similar attacks to the present. The attacks lasted for from one to four weeks. He had had three attacks since January last. The attack preceding the present one occurred in July last and lasted for four weeks. After that he was quite well until the present attack began. The pain during the attacks had become worse. When questioned about the pain he was quite definite as to its coming on from one hour to an hour and a half after meals, that it got gradually worse till he took food again, when he obtained relief for about an hour, when it would begin again. The pain was worse after solid food than after liquids. It was now burning in character, and was most severe at points midway between the xiphoid and the umbilicus, and in the angle between the last rib and the spine, but also in the hepatic region between these points. After food he had a sense of weight in the epigastrium. The bowels had been very constipated for five years, and he had had to take laxative medicines all that time. He had vomited a few times—the last occasion was three weeks previous to admission and occurred about an hour after food, the pain being relieved by it. The appetite was poor and he was not inclined to take food. The attack which he had in July left him very weak and thin, and between that and the present attack he did not put on much flesh. He had become much thinner since the present attack began; he had been off work for three weeks and had been in bed during most of the time. He was questioned more directly about vomiting and as to the character of his motions, and the following facts were obtained; and although it was impressed upon him that he must be quite certain of their accuracy he steadfastly adhered to them. He had not vomited blood or dark material during the present attack, but ten days previously his motions were black like tar, although he was taking no medicine save seidlitz powders. He vomited coffee-ground material two months ago and he had vomited similar-looking stuff before. The motions were black a month ago and also in July; in fact, he seemed confident that his motions were often, if not always, black during the attacks. On examination of the abdomen there was a degree of tenderness all over it, with a degree of rigidity of its walls; it was more tender at the spots mentioned above as points to which pain was referred and over the hepatic region. The stomach was not enlarged. A test breakfast showed abundant free hydrochloric acid.

Remarks.—The special points to be noted in this case are that the gastric attacks had lasted for five years and had recently become worse and more frequent. The history of the gastric symptoms points to hyperchlorhydria dyspepsia; there were periods of freedom from trouble, followed by periods during which pain came on from an hour to an hour and a half after food; was relieved by taking food for an hour or longer, but again returned. The patient had had three attacks since January. He had had an attack in July which lasted four weeks; then he had had a period of comfort until the present attack began four weeks before admission. The attacks were sufficiently severe to lay him up and loss of work had become a serious matter with him. He was very confident in asserting that he had frequently had tar-like motions and that he had on some occasions vomited material like coffee-grounds. There had been no melæna and no hæmatemesis since admission. There was no difficulty at the pylorus leading to the attacks.

contents. There was no dilatation or displacement of the stomach. The stomach contents withdrawn by the tube showed abundant free hydrochloric acid. The patient was so very positive about the tar-like motions that his statement must, I consider, be accepted as a clinical fact. The frequency of the attacks, their intractability to weeks of treatment, however imperfect it may have been, and the position and character of the pain, all tend to open one's mind to the acceptance of the patient's assurance regarding the character of his motions and perhaps of his vomit also. If the facts have been correctly obtained, if our evidence is reliable, they point to duodenal ulcer. And if we are to have the courage of our diagnosis, this is also a case for gastro-enterostomy. I am one of those who believe that when you make a diagnosis of duodenal ulcer it is wise to advise operation, especially if, as in this case, there has been recurrence of symptoms. The unsatisfactory point regarding operation is that the ulcer will not be seen, even at the operation, unless it be on the anterior wall; and, in this case, it is probably on the posterior wall. So the surgeon, even though he may accept the diagnosis, does nothing to establish its accuracy. The operation of gastro-enterostomy was performed by Mr. Caird on Sept. 29th. There was no ulceration of the stomach found and no obstruction at the pylorus.

CASE 3. *Malignant disease at the pyloric end of the stomach.*—The patient, a married woman, aged 43 years, was admitted to the Edinburgh Royal Infirmary on August 20th, 1906, complaining of uneasiness in the stomach and vomiting, the symptoms having lasted since June last. The history of her present illness dated from early in that month, when she began to suffer from sensations of uneasiness shortly after taking food, the food often regurgitating, but there was no vomiting. The sensations came on, as a rule, from half an hour to an hour after each meal. She had also been constipated. Before June no history of any kind of gastric or digestive disorder could be obtained by the most direct questioning. She had become gradually worse, treatment giving her no relief. The eructations had increased; vomiting had begun and had become more frequent. As she was rapidly becoming weaker and losing flesh she came to the infirmary. She had noticed some time ago a lump in the upper part of the abdomen. Examination of the alimentary tract showed her gums to be edentulous, the result of complete extraction, and the tongue was flabby with a slight fur. The appetite was fairly good. After meals there was a feeling of tension in the abdomen, and she was conscious of movements and rumblings in its upper part. She felt drowsy and heavy after food. She vomited frequently after admission, the vomit consisting of the food she had taken but little altered, and when she was allowed bread the vomit contained great pieces of undigested bread crust. Ultimately we minced all her food, but that only led to a temporary diminution in the frequency with which she vomited. The vomit never contained free hydrochloric acid, nor did the gastric contents withdrawn by the tube after a meal. There was a pear-shaped lump to the right of the epigastrium, moveable, and not seemingly adherent to deeper structures. The smaller end of the lump was to the right. The stomach was considerably dilated, its inferior border reaching to the umbilicus and the fundus to the fifth rib.

Remarks.—This case differs from the two preceding cases in this, that there is what is commonly called a tumour in the upper part of the abdomen. It is a somewhat pear-shaped swelling, running from above downwards and to the right, the smaller end being its right inferior end. The mass is usually hard, easily felt, and to a small extent moveable. The stomach is dilated, its boundaries being easy to define by succussion and percussion in the manner which I showed you in Case 1, which I repeat here, and which some of you can come forward and confirm. The succussion wave can be felt right up to this mass. A point of clinical interest is that this mass alters in character; it becomes so soft that it requires the expert hand to be sure of its existence. Farther, waves of stomach contraction are often to be seen passing across the upper part of the abdomen and ending in the mass. The mass is the thickened wall of the pyloric end of the stomach—its position, shape, altering thickness, and its relation to the greater and lesser curves of the stomach all confirm this. There have been no hamatemesis, no coffee-ground vomit, and no melaena. There was an entire absence of symptoms until June last, but once they had begun they had a remission in them;

discomfort and vomiting, especially vomiting, have become pronounced. The vomit and the stomach contents removed by the tube have never shown a trace of free hydrochloric acid. That there is pyloric obstruction is shown by the retention of food in the stomach. That the stomach is not larger than it is and that there is no marked fermentation of its contents are due to the ease and regularity with which the stomach has hitherto emptied itself by vomiting when discomfort became considerable. The diagnostic points in the case are the "tumour," which varies in size and hardness and might be said at times to disappear on gastric peristalsis, and vomiting. These three points indicate pyloric obstruction, with marked spasmodic contraction of the pylorus. The two conditions which give rise to pyloric spasm, as marked as it is in this case, and to vomiting, are simple ulcer and malignant growth near the pylorus. There is no history of simple ulcer here nor are the symptoms those of simple ulcer near the pylorus and therefore we conclude that there is malignant growth here. The onset, the course, the present condition, and the absence of free hydrochloric acid all support this. A great part of the difficulty commonly experienced in making differential diagnosis in gastric and abdominal disease is really due to a want of definite knowledge as to the lesions which occur in different viscera, as to the symptoms which are practically inseparable from each. In this case there is no doubt that the "tumour" is the pyloric end of the stomach. I once, after a hurried examination, thought a "tumour" of this nature a displaced kidney, but I speedily rectified my error. The pylorus is the site of the "tumour," and if we consider next its nature we conclude that much of it must be due to muscular contraction of the pyloric wall, for it goes and comes to a considerable extent. This is not uncommon. As to the explanation of the muscular spasm, it is, in my experience, due to irritation caused either by a chronic open ulcer near the pylorus or to an infiltrating cancer in the same region. We exclude simple ulcer, and when this is done there is no escape from the alternative. If we have gone so far we would be sheer affectation were I from this point to play ignorance. If this is malignant there is only one method of treatment of any avail and that is removal. If removal were not possible I would not advise operation, but owing to the mobility of the "tumour" we hope it may be found removable. What particular operation is to be performed belongs entirely to the surgeon. This patient was also operated on by Mr. Caird on Sept. 29th, when a pylorotomy was done followed by a gastro-enterostomy. The pyloric end of the stomach showed much thickening and contraction of the pyloric muscle, while near the pyloric opening there was one of those large circular growths, with a raised fungous margin and an atrophied-looking centre, which we commonly regard as malignant. There was no affection either of the lymph glands or of the liver so far as could be seen.

Sections of the removed pylorus made by Mr. How Wade, one of the assistant pathologists, showed the condition to be an infiltrating cancer.

These three patients made uninterrupted and rapid recoveries and were able to return to their homes in the course of from three to four weeks.

Edinburgh.

A CASE OF PARATYPHOID FEVER IN MAURITIUS.

By D. B. SPENCER, L.F.P.S. GLASG., L.S.A.,
LIEUTENANT-COLONEL, I.N.S.;

AND

H. E. STADDON, M.R.C.S. ENG., L.R.C.P. LOND.,
CAPTAIN, R.A.M.C.

THE patient, a European, aged 30 years, an assistant surveyor on the Royal Engineers' civil staff at Mauritius, came under our joint care about the end of September, 1905.

History.—The patient left Dublin on August 2nd, 1905, being then in perfect health, and arrived at Mauritius on Sept. 22nd, having had a sea voyage of 52 days. *En route* he disembarked at several places—namely, Southampton, Tenerife, Cape Town, Port Elizabeth, Durban, and Delagoa Bay, staying only for a few hours on shore at the first four places but for five days at Durban and for a full week at Delagoa Bay. He was perfectly well until he arrived at

Severe epistaxis on Oct. 12th and 13th. During the period from Oct. 20th to Nov. 4th inclusive the patient's condition was critical though his temperature was not high. On Nov. 18th and 19th there was a passing rise of temperature, due to stomach derangement.

Delagoa Bay, but when two days out at sea from the bay, and about Sept. 19th, he first felt ill, the symptoms being a feeling of chilliness, loss of appetite, some headache, and general aching in the body, with depression of spirits and low fever. These symptoms persisted more or less to the end of September when he went to bed with high fever and came under our joint care. He had never suffered previously from either enteric or malarial fever and had never been inoculated against enteric fever. There was no case of fever on board ship during the voyage. The patient's family history was good; he belonged to a healthy long-lived family and had scarcely known any illness in his life, except a mild attack of fever in the West Indies, which lasted for three days and which he was certain was not malarial fever.

Progress of the case.—Taking Sept. 19th as the starting point of the disease as explained above, Oct. 3rd would represent the exact date of the beginning of the third week of the disease and from this latter date the temperature chart and other particulars of the case were duly recorded by us.

Third week (Oct. 3rd to 9th): The chief symptoms of this week were high fever of the continued type, as shown in the accompanying temperature chart, with headache and loss of appetite. There was no eruption, the internal organs were normal, and there was some constipation. The mind was clear.

Fourth week (Oct. 10th to 16th): The chief symptoms were high fever of the continued type, a little diarrhoea, severe epistaxis, a dry tongue, and a drowsy expression. The abdomen was nearly normal, there being just a little fulness but without any pain or tenderness anywhere. The mind was perfectly clear.

Fifth week (Oct. 17th to 23rd): During this week the fever persisted, but with a downward tendency during the early part of the week. During the latter part of the week, however, the fever, instead of going down as was expected, took an upward course, and this, in conjunction with some evidence of gastro-hepatic irritation which was then present, pointed to secondary infection of the liver. The liver, therefore, was frequently examined at this stage but nothing abnormal was detected at any time. The tongue was very dry as in the previous week and this was a noticeable feature of the case. The bowels were now regular and normal. The mind was perfectly clear.

Sixth week (Oct. 24th to 30th): The fever during this week, though not high, was a source of some anxiety, as there was nothing to account for it, while the patient was getting rapidly emaciated and debilitated with the exhaustion from the fever and the low diet, consisting of milk and barley water, which was practically all he had throughout his illness.

Seventh week (Oct. 31st to Nov. 6th): The temperatures both morning and evening during this week were near the normal line. Convalescence was established. The general condition was favourable. The temperature reached the normal line for the first time during this week on the forty-fourth day of the disease. It may be stated here that to guard against error the temperature was taken at different hours of the day and night and that it was never normal, showing that the fever was of the continued type.

Eighth week (Nov. 7th to 13th): There was nothing particular to note during this week. The morning temperatures were normal, while there was a slight rise of temperature in the evenings. The general condition was favourable.

Ninth week (Nov. 14th to 20th): There was a slight rise of temperature during this week which was due to a passing derangement of the stomach. Recovery was uninterrupted after this date.

Treatment.—Briefly speaking, an attempt was made at the start, Oct. 3rd, to make the disease abort by flushing the large intestine with tepid water pinked with Condy's fluid and by hypodermic injections of quinine, but the disease had advanced too far for this abortive treatment to be of much use.¹ An expectant treatment was now adopted. Burney

¹ In THE LANCET of Sept. 23rd, 1905, p. 574, Captain F. P. Mackie, I.M.S., in reporting his case of paratyphoid fever has referred to my abortive treatment for this disease and has quoted me as follows: "By this means I have never failed to bring the case to a favourable termination by the end of the second week." In order to prevent any erroneous impression it is, I think, necessary to add as follows: "If the treatment be commenced not later than the fourth or fifth day of the disease." The abortive treatment is, I think, applicable at a very early stage of paratyphoid fever and when so applied the results have been uniformly successful in my hands and I shall be glad to demonstrate the treatment before any medical society or any competent authority I am invited to do so.—D. B. S.

Yeo's quinine and chlorine mixture was given and was well borne. Tepid sponging of the body was of great use. The symptoms of gastro-hepatic irritation were relieved by a few doses of bismuth and soda. Epistaxis was controlled by ergot and calcium chloride. The diet was almost entirely of milk and barley-water in equal parts.

Bacteriological examination of the blood.—Through the kindness of Dr. F. A. Rouget, superintendent of the Civil Hospital at Port Louis, Mauritius, the following report was obtained: "We have tested the samples of blood with fresh cultures of the bacillus typhosus and the bacillus coli communis and in both cases the reaction was negative. The observations were made with cultures 18 hours old and in each case a 1 in 50 dilution was used according to the process generally adopted. In presence of the negative results obtained it was not found necessary to continue the experiments with 1 in 200 and 1 in 500 dilutions. We can give you no further information, as we do not possess cultures of the micrococcus Melitensis or of the Gaertner group."

General remarks.—Although clinically the case was one very similar to a case of true typhoid fever there were some important differences—namely, the sporadic nature of the case, the absence of a marked typhoid state, and the absence of any abdominal symptoms pathognomonic of true typhoid fever, such as would be expected in a case lasting over nine weeks. Among other symptoms, perhaps less important but still valuable aids to a diagnosis of true typhoid fever, we may mention the rose-coloured eruption in successive crops, enlargement of the spleen, and deafness which were all absent in this case. Taking these negative symptoms in conjunction with a negative Vidal test we venture to think that this was a case of paratyphoid fever, while we regret our inability to give some positive evidence as to the causation of the disease owing to the limited means at our disposal for a detailed bacteriological examination of the blood.

ON WHITE-WINE WHEY IN INFANT FEEDING.

BY BERNARD E. MYERS, M.D. EDIN., M.R.C.S. ENG.,
L.R.C.P. LOND.,

AND

GEORGE F. STILL, M.D. CANTAB., F.R.C.P. LOND.,
PROFESSOR OF DISEASES OF CHILDREN, KING'S COLLEGE, LONDON.

AMONG the many foods which are occasionally of value in infant-feeding sherry whey, or "white-wine whey" as it is sometimes called, must hold a high place, not because it has any particularly large nutritive value but because it combines certain properties which are of great importance under certain conditions. Like the ordinary whey prepared with rennet the whey made with sherry is easily digestible owing to the removal of the milk-curd in the process of preparation; and, like the rennet whey, it has also lost a large proportion of the milk-fat owing to its entanglement in the curd which was strained off. The curd, however, from sherry whey is flocculent and thus unlike the curd *en bloc* produced by rennet; the fat also for this reason is less completely entangled and the proportion remaining in the sherry whey is as high as that in a rennet whey, in which special precaution has been taken to liberate the fat so far as possible by breaking up the curd before straining. Our own analysis of sherry whey, prepared as will be described below, showed proteid 0.45 per cent., consisting almost entirely of the easily digested lactalbumin, fat 0.95 per cent., and there is also present (but not estimated by us) sugar about 5 per cent. The sherry whey therefore is, like rennet whey, a food low in nutritive value, but such as might be expected to agree well where there is difficulty in digesting the stronger preparations of milk. But sherry whey has other properties which do not belong to the ordinary rennet whey. The sherry which is used in its preparation gives to the white-wine whey its peculiar flavour which is said to be due to the presence of essential oils or volatile ethers in the wine, constituents which probably contribute to the carminative effect which is one of the virtues of this food.

Sherry whey has also a markedly acid reaction, and it would seem from the good results of buttermilk and of other preparations in which lactic acid fermentation has been artificially induced in milk that acidity of the food, so far from being harmful, is sometimes beneficial in infant feeding.

Sherry owes its acidity chiefly to tartaric and acetic acids, its curdling action upon milk is due to this acidity, however, vary in their acidity, and it is matter of knowledge that a "drinking sherry" curdles milk readily than does a "cooking sherry." We found that from three to four ounces of drinking sherry required to curdle half a pint of milk, which curdled by two and a half ounces of cooking sherry is a point of some practical importance, for, as we show, the proportion of alcohol in sherry whey the cooking sherry is quite as high as in drinking sherry, not desirable, therefore, to use drinking sherry, only contains more alcohol but must be used in quantity. Actual estimation showed the difference to be as follows:—

	Fixed acid (estimated as tartaric).	V
Drinking sherry (2s. 1d. per bottle) ...	0.348 per cent.	0.077
Cooking sherry (1s. per bottle) ...	0.352	0.081

Sherry whey, prepared as described below with this sherry, showed fixed acid (tartaric) 0.067 per volatile acid (acetic) 0.015 per cent. More, however, than the acidity is the alcohol, which gives food its stimulant effect, and we have made some estimations to determine the exact amount of alcohol which might be conjectured from the mode of preparation. The part of the alcohol contained in the sherry would volatilise during the heating of the food, the amount so lost and the amount remaining in the whey could find no information in any text-book.

The method of preparation which after being fixed upon as the most satisfactory is this: ten ounces of milk were heated until just boiling, then two and a half ounces of cooking sherry were added and heat was again until the mixture began actually to "boil up," it was removed from the fire and allowed to stand for ten minutes; the curd was then strained off through a layer of butter muslin. The alcohol in this whey, estimated by the usual method of distillation and estimation of the specific gravity in the distillate. Estimation also made of the alcohol present in the sherry used in case. Drinking sherry (2s. 1d. per bottle) was found to contain 16.46 per cent. of alcohol by weight. Whey, with this (three ounces of sherry were necessary as no amount would curdle) contained as nearly as possible 1.5 per cent. of alcohol by weight; and as the dilution of sherry by the milk would make the percentage 3 per cent., it is seen that 0.73 per cent. of alcohol was lost in preparation. A cooking sherry, costing 1s. per bottle, contained 14 per cent. of alcohol by weight; whey with (using two and a half ounces as described) contained 2.28 per cent. of alcohol by weight. The dilution of sherry by the milk in this case would have made the portion of alcohol 2.8 per cent.; in this case, 0.52 per cent. of alcohol was lost in the preparation of whey. Another cooking sherry, costing 1s. 3d. per bottle, was found to contain 14 per cent. of alcohol by weight; whey made with two and a half ounces of this sherry, a pint of milk showed 2.28 per cent. of alcohol by weight, one experiment and 2.3 per cent. in another. Here, the loss of alcohol in the preparation of the whey was approximately 0.5 per cent.

For clinical purposes brandy is a convenient comparison in considering the alcoholic value of this whey. An average brandy contains 42.5 per cent. of alcohol by weight, so that if sherry whey be reckoned as containing 1.5 per cent. of alcohol by weight, it is approximately one-eighth (strictly $\frac{1}{8}$) of the strength of brandy; one ounce of sherry whey is therefore, so far as concerned, equivalent to 25.8 minims of brandy. The use of sherry whey, therefore, it must be said, that it is a food which contains a considerable amount of alcohol.

The conditions in which this food is suitable for an infant are those in which only small quantities of food can be tolerated and where a stimulant is necessary. Where there has been much vomiting, with or without diarrhoea, an infant has already been fed for some hours with water or veal broth in small quantities, sherry whey makes a useful step towards the return to milk. Sometimes, indeed, in the acute stage where there is much vomiting a drachm or a few drachms of this food may be retained in the stomach when other foods have been

In cases where owing to difficulty of milk digestion has been chronic vomiting and the infant has become exhausted, feeding for two or three days on small quantities of sherry whey alone, and then on alternate feeds of whey and fully peptonised milk, is sometimes of great benefit. In the common cases where food after food has been refused and the infant has become emaciated and screams with colic and colic after meals sherry whey sometimes has a good effect in reducing the flatulence and colic, and so relieving the child's distress; in such cases it may be given in alternate feeds for several days and then two or three times a day. We have seen excellent results from it also in the case of premature or very feeble newly born infants. A quantity of sherry whey which can be given is determined chiefly by the proportion of alcohol which it contains. It is not intended for prolonged use but we often use it as the only food for a week or ten days and when it is given at alternate feeds only it can be continued if necessary for two or three weeks. To an infant six weeks old a tablespoonful can be given every half hour or three-quarters of an hour and the amount and interval gradually increased until two ounces are taken every two hours.

The quantity, however, as a rule is determined less by the age of the infant than by the general condition and degree of tolerance shown by the stomach. At any period when it is seldom desirable to exceed from two to two and a half ounces of sherry whey at a feed; but in exceptional cases we have given as much as three ounces every two hours to infants about six months old and even four ounces every three hours to an infant 12 months old for two or three days with great benefit. As a general rule it should only be laid down that sherry whey, like any other fluid which contains alcohol, should never be given to infants in any quantity or continued for a longer period than the necessities of the case require.

SCLERODERMIA AND MYOSITIS.¹

J. A. NIXON, M.B., B.C. CANTAB., M.R.C.P. LOND.,
PHYSICIAN TO THE FEET DEPARTMENT, BRISTOL ROYAL INFIRMARY.

Three years ago I contributed to the *Bristol Medical-Chirurgical Journal*² an account of a case of muscular atrophy with scleroderma, in which the evidence that the changes in the muscle were primary—either of the nature of a progressive atrophy or a dystrophy—was irresistible. In publishing that case four other patients have come under my observation at the Bristol Royal Infirmary whom I wish to provide material for a further study of these conditions and to throw fresh light on their nature. Of recent years, too, other cases have been recorded which make it evident that the associated affections met with in scleroderma are no longer the isolated conundrums which they formerly seemed. From a careful clinical investigation of a number of cases under my own care and from the published records of other observers I think that there is beginning to be collected a considerable amount of evidence that the muscular changes of scleroderma are (together with the skin changes themselves) merely a local manifestation of a general disease, an infective inflammatory affection resembling in many points the rheumatic infection.

Just as in acute rheumatism we are familiar with the usual form of a general shifting synovitis, varied at times by an attack on serous and especially cardiac membranes, manifesting itself sometimes by localised tendinous infiltrations of a nodular type, at others by subcutaneous erythematous inflammation, or again appearing in cerebral form as chorea, there is evidence of an analogous polymorphism in the disease which for convenience may be termed generally scleroderma. There is little need to describe the clinical appearances of scleroderma, the localised form with its thick, glossy, hard, ivory skin, or the generalised form with its more or less widespread "hidebound" appearance, thick, immobile, parchment integument, with the natural folds of the skin obliterated, and expression lost in the face giving rise to the "masque sclérodémique."

Of the pathology much has been written and little explained. Briefly, the cellular elements of the skin disappear, together with the elastic and fatty tissue, the vessels become

narrowed or obliterated, and the collagenous bundles hypertrophy. Ultimately the whole affected area becomes atrophied into a thin parchment-like cutaneous plate without a papillary layer or subcutaneous tissue but covered with atrophied epidermis.³ Nerve lesions have been reported but the evidence of any constant nervous origin for this affection is still lacking. In such cases as have been examined after death the muscle changes have been variously reported to have been either of an inflammatory nature, "myositis diffusa," or, in what may be interpreted to be a later stage, of the nature of a fibrous degeneration or infiltration, "myositis fibrosa." It must be confessed that the necropsies on record throw little or no light so far on the etiology of the disease. We are thrown back again on the living subject, to an investigation of the clinical phenomena, to an examination of analogous diseases and allied conditions, and perhaps to a research into the manner of discharging the vital functions. Bloch and Retmann⁴ have recently published their researches upon metabolism in scleroderma and state that there is no characteristic variation in the Nitrogen-exchange. By correlation of these one with another and by comparison or contrast with the processes observed in other diseases it may be possible to arrive at some definite conclusion as to what scleroderma is and how it arises. Although the four cases described may be quite wrongly associated, although the suggested points of similarity may be quite wrongly interpreted, still there remain some features in common which bespeak the same pathological processes underlying them.

CASE 1.—A healthy girl, aged 13 years, first came under the care of Dr. H. Waldo 18 months ago on account of a patch of painful, thickened, stiff, glossy skin on the right shoulder and arm, a narrow band extending from the posterior aspect of the acromion over the deltoid and down the outer and posterior part of the arm to a point a few inches below the elbow. It did not at first occupy so large an area as this but spread rapidly in the first week or so, then became stationary, and finally began to disappear, especially behind the shoulder where now the skin is practically normal; the white waxy appearance showed itself almost at once. Three months ago she developed a similar smaller patch about two inches long and one inch wide, oval in shape, on the left thigh just over the apex of Scarpa's triangle, and now she is developing some indefinite thickening of the skin on the inside of the left knee just above the condyle of the femur. Also within a month or two of first attending the right hand was noticed to be smaller than the left, while the middle finger, although freely moveable as regards the joint, was incapable of being completely extended unless the wrist was flexed. The muscles of the forearm were not noticeably wasted nor lacking in power; flexion and extension of the fingers were perfectly normal up to a point where the tendon of the flexor sublimis digitorum to the middle finger seemed to be stretched to its utmost and the finger could be no further extended, the flexion only being apparent at the metacarpo-phalangeal joint. This is the condition at present: there are no involvement of tendon-sheath or fascia as in Dupuytren's contraction and no true primary muscular atrophy, all electrical reactions are normal, and it is neither a spastic contraction of the flexor muscle nor due to defective power in the extensor. This seems to be an essential shortening of muscle and tendon. The girl herself was not aware of any abnormality in this hand. There was no acute onset, no rheumatism, no pain, no tenderness, anesthesia, or any symptom to attract the patient's attention.

CASE 2.—The patient was a single woman, aged 40 years, in domestic service. She showed changes in the skin of her left arm and hand which dated either from birth or very early infancy. She had true sclerodactylia, the thumb and first finger of the left hand were deformed, the skin was thickened, hard, and cold but not white, and even the bones were irregularly thickened as if by periostitis. The skin was chiefly involved up the radial border of the forearm to a point just above the elbow so that on straightening the arm a thick fold of infiltrated skin was made tense and prominent, yet there was no implication of muscle or tendon in this part; but on the palmar aspect of the first metacarpal, where the skin was scarcely at all affected, the

¹ Fibromatosis or new formation of collagen fibres takes place not only in association with granulating wounds but also in a large number of affections of the corium. After recurrent attacks of lymphangitis and erysipelas where a persistent oedema has occurred the oedema causes a rarefaction of the fibrous stroma, which is followed by a fibromatous process. In scleroderma the hardness is due to a hypertrophy of the fibrous tissue. Pathology of Skin Diseases, Macleod, p. 115.
² Bloch and Retmann. Wiener Klinische Wochenschrift, vol. xix., p. 630.

¹ A paper read at a meeting of the Bristol Medical-Chirurgical Society on Nov. 14th, 1905.

² Bristol Medical-Chirurgical Journal, December, 1903.

tendon of the flexor sublimis showed the characteristic contracture; the skin, fascia, and tendon sheath were all free from induration, yet the tendon was distinctly shortened, and on straightening the finger with the wrist and elbow extended it stood out as a thin cord tightly stretched. Quite recently this patient had severe pain and tenderness over the roots of the brachial plexus, but this had subsided without further change in skin or muscle.

CASE 3.—The patient was an unmarried woman, aged 22 years, the subject of a large goitre without symptoms of Graves's disease. Two years ago she was taken ill with an attack of rheumatism; not quite characteristic rheumatic fever, for there seemed to have been no effusion into the joints, only pain, severe pain, all over and inability to move the limbs. Recovering from this all her joints were found to be stiff and apparently enlarged, looking at first sight like osteo- or rheumatoid arthritis. But on examining the joints they were found to be limited in their movements; not by essential changes in the joints themselves, but by a general shortening of flexor tendons, of such a nature that if an attempt was made to straighten the various joints of the fingers, the wrist, and the elbow simultaneously the tendons became tense and complete extension was prevented; while flexion of the elbow immediately allowed the wrist to be extended. Further, the apparent expansion of the articular ends of the phalanges was shown by a radiogram not to depend upon bony changes but upon wasting of the soft parts. The muscles and tendons of the upper extremities alone showed these alterations and the electrical reactions were everywhere normal. In this patient the tendon sheaths and fascia were free and there was no sign of any skin affection. Although there was a goitre present without symptoms of Graves's disease, yet very small doses of thyroid extract or thyroidestin produced immediately tachycardia, nervousness, and tremor.

CASE 4.—The patient was a girl, aged 20 years, who previously was in good health and had suffered from no skin complaints. Two months ago she scratched her right arm. From this a general inflammation followed, apparently an ordinary attack of erysipelas, for which she was admitted to the Royal Infirmary. Now that the erysipelas had subsided there was over the insertion of the deltoid an induration of the skin about 6 inches long and 3 inches wide, roughly oblong in shape, slightly swollen, dusky red in colour but mottled with white streaks and stellate veins, surrounded by the "lilac ring." The edges were well defined but beyond the margin subcutaneous "islets" of infiltration could be felt which did not involve the epidermis. The skin did not feel adherent to the subjacent tissues, nor were any muscles affected. There was no pain and sensation was unaltered. The case seems to be one of localised scleroderma or morphea following directly upon erysipelas or starting from an infected wound. (At the present time this patient is suffering from an attack of articular rheumatism with acute endocarditis.)

The case which I reported three years ago is worth calling to mind in this connexion; to quote from the description then given, "The first symptom complained of was a weakness in the limbs; at first the left hand felt weak and numb, especially towards night later the right hand followed suit and aching pains were constantly present in the forearms. Soon after, the legs began to ache on walking short distances so much that after a five mile round he was obliged to lie down and rest. The tips of his fingers started tingling and were so sensitive that he gave up shoe-making, after vainly trying to relieve the tenderness by wearing woollen gloves." It was some months before any changes in the skin were noticed. Then the scleroderma became gradually of the generalised type; there was atrophy of the muscles and marked contraction of some of them, notably the biceps, "which could be felt as a tense cord, no thicker than the little finger, lying under normal elastic skin which could easily be raised from the underlying muscle"; the right arm was flexed at an angle of nearly 90° at the elbow, while a lesser degree of wasting and contraction was shown in the left arm. Many other muscles had atrophied but none contracted like the biceps.

To Thibierge is due the credit of first seriously attracting attention to the changes in muscles associated with scleroderma* and more recently in *La Pratique Dermatologique*† he quotes Leredde and Thomas to show that the

only well-established point in the pathogeny of the disease is that a sclerosis of the skin, possibly inflammatory in origin, is always present. A brief epitome of cases collected by Thibierge† is appended.

1. Girl, aged 17. Diffuse scleroderma on plaques. Scleroderma. Triceps wasted, movements free but feeble can be flexed but not extended fully owing to contraction of General loss of power in hands and fingers, not depending on Sclero-mastoids contracted. Peri-articular (scapulo-humeral) adhesions. R.D. in some muscles.

2. Woman, aged 23 (Westphal L.). Diffuse scleroderma. Scleroderma. Onset unnoted. Left elbow cannot be extended owing to contraction of biceps which is as hard as wood. Her fingers half flexed in position of repose, and although the joints relatively more freely moveable than usual flexion is very limited. No pain, some crepitation round joints, articular surfaces feel rough. Leg muscles very hard, no true contraction, movements of limited. No paralysis.

Necropsy.—No joint changes. Fibrous peri-myositis, no intermyositis.

3. Woman, age 36 (Westphal II.). Diffuse scleroderma. Scleroderma. Many muscles atrophied although skin is free from traction in biceps similar to foregoing.

4. Woman, aged 53 (Goldschmidt). Sclerodactylia. Nasque dermique. Symmetrical gangrene. Skin of neck free. Muscles and tendons ("soudés") in the forearm; on movement dry creaking felt.

Necropsy.—Peri-muscular fascia very dense, inter-muscular spaces show increase of fibrous tissue. Some atrophy of the fibres.

5. Man, age 19 (Schultz). A fatal case of Addison's disease scleroderma and interstitial myositis.

Of other published cases I have been able to collect the following:—

6. Hutchinson.⁸ A case of scleroderma with contraction of mastoid not due to induration of the skin.

7. Grasset.⁹ Scleroderma with fibro-tendinous contractions of muscle atrophy, not myelopathic nor neuritic, but a "myopathy."

8. Elliott.¹⁰ Amyotrophic changes preceding scleroderma 1 years.

9. Pelizaeus.¹¹ Scleroderma with independent sclerosis of muscles. 10. Rosenfeld.¹² A similar case.

11. Haushalter and Spillman.¹³ Girl, aged six. Diffuse scleroderma accompanied by marked atrophy of muscles and a growth in one leg.

12. Herringham.¹⁴ A man with scleroderma and a condition resembling rheumatoid arthritis but depending actually on muscular contractions, not joint changes; all the limbs contracted.

13. Fowle.¹⁵ Diffuse scleroderma with widespread tendons.

14. Batten.¹⁶ In a very complete description of myositis quotes a case of Lindner in which typical myositis fibrosa was associated with sclerosis of the skin.

15. Potjes and Olejat.¹⁷ A fatal case of five years' duration woman who developed the most extensive scleroderma and through a generalised acute myositis to a stage of fibrous contracture Scleroderma with myositis diffusa (necropsy).

Now the dependence of scleroderma and the allied cutaneous atrophies upon nerve lesions is at best only a matter of conjecture; in the majority of necropsies no changes in the nervous system have been found; in the few instances in which these changes did exist they were of an inconstant, even contradictory, type that no causal relationship could be established between nervous system, skin muscle. But the evidence of primary inflammation in the muscles of either an acute or chronic variety, ending in a fibrosis, is amply corroborated both by clinical and pathological facts. Beyond this it is difficult to penetrate, the indications seem to point to an acute or chronic infection which affects mainly muscle and subcutaneous tissue, resulting in a sclerosis of the skin and the muscles an infection to which perhaps persons suffering from other general diseases are peculiarly liable and especially subjects of Graves's disease, myxoedema, Raynaud's disease, Addison's disease, and nerve degenerations. It is probable that myositis of a localised nature going on to sclerosis and contraction of a single muscle or a group of muscles is commoner than generally supposed; and the disease, of which this is only one manifestation, may be acute, subacute, or chronic course, and on occasions involve the skin, giving rise to one type of scleroderma reference to the original monograph of Addison.

of Alibert and True Keloid¹⁸ makes it obvious a disease as seen and described by Addison under the title was not, as has always been represented, solely a primarily a cutaneous disease, for he recognised and named in two of his cases a general sclerosis of muscle, and fascia, together with—and as part of the same process very nearly allied to inflammation, probably a stromous nature"—true keloid of the skin which he called sclerodermia.

c. Bristol.

RUPTURES OF THE URETHRA, INTRAPELVIC AND PERINEAL.

EDWARD DEANESLY, B.Sc. LOND., F.R.C.S. ENG.,
CONSULTANT SURGEON, WOLVERHAMPTON AND STAFFORDSHIRE
GENERAL HOSPITAL.

An article published in 1894¹ I pointed out that ruptures of the urethra associated with fracture of the pelvis presented anatomical and clinical peculiarities not at that time fully recognised, although they are of great importance. In text-books of that date the common injury of the urethra caused by direct violence, such as kicks in the perineum or falling astride, was described as a partial or complete rupture of the membranous urethra, or of the portion immediately in front of the triangular ligament; and the rupture was attributed to violent compression of the urethra between the pubic arch and the object causing it. By the same authorities injury of the urethra in the female pelvis was attributed to laceration by the sharp points of the broken pubic arch. In both cases the same of the urethra was said to be affected—namely, the membranous—and in both it was said to be accompanied by rupture of the anterior layer of the triangular ligament. I followed the familiar description of the course taken by extravasated urine; how it distended first the anterior part of the perineum, then the scrotum, and afterwards the soft tissue of the groins and lower abdomen, as a natural result of the disposition of Colles's fascia.

My own observations and dissections published in 1894¹ need me that this classical account of the anatomy of the clinical sequelae of ruptured urethra contained much. The description of the text-books was quite correct as it applied to direct injuries of the perineum by falls or kicks. In the slighter cases of this sort the injuries consist of more or less bruising of the bulbous portion of the urethra, sometimes with internal mucous lacerations; in the severe cases the membranous urethra is torn completely and immediately in front of the triangular ligament. In cases of sort extravasation of urine, if it is allowed to occur, it follows the route determined by the attachment of Colles's fascia, just as it does in an ordinary case of neglected fracture in the bulbous portion. When, on the contrary, rupture of the urethra occurs in a case of fracture or violent compression of the whole pelvis the position of the rupture and the course of extravasation are quite different. In every case of pelvic injury which I have examined and in all published cases known to me which are accurately described the rupture when injured has been torn on the upper or posterior part of the triangular ligament—i.e., where the membranous urethra enters the apex of the prostate. In other words, the rupture in these cases is not perineal, but intra-pelvic. The extravasation of urine when it occurs is also intra-pelvic and blood collect in the prevesical space without any rupture of the perineum, though the skin of the latter may be ecchymosed. The two different positions in which the membranous urethra is ruptured by direct and indirect causes respectively will be easily understood by reference to Figs. 1 and 2.

The exact mode in which what we may call the intra-pelvic rupture of the urethra is brought about is not entirely clear. In the majority of cases of fractured pelvis which have come under my observation the fracture has been caused by lateral compression of the pelvis; for example, a fall between two tubs in a coal mine or between a railway carriage and a platform. The other common causes of fracture of the pelvis are falling from a great height and being run over between the ground and some heavy falling mass,

such as rock or masonry. In such accidents the blow or compression is as likely to be antero-posterior as lateral, but cases of the latter are obviously less likely to be immediately fatal, and this may account for their greater frequency in surgical practice.

Now, the effect of a sudden violent lateral compression of the pelvis must be to shorten its transverse and to lengthen its antero-posterior diameter until the bony ring finally

FIG. 1.

Normal relations of the pelvic fascia.

gives way at its weakest parts. The lengthening of the antero-posterior diameter necessarily puts a violent stretch on all the soft parts in the median sagittal plane and tends to detach them from the back of the pubis. As the triangular ligament is firmly attached to the pubic arch it practically forms part of the bony pelvis and moves forward with it. The urethra, therefore, gives way just where it emerges from the triangular ligament on its upper or pelvic side and enters

FIG. 2.

Rupture of the urethra above the triangular ligament. The shaded area shows the position of the extravasation.

the apex of the prostate. In many cases the pubo-prostatic ligaments are also torn and then the bladder and prostate fall back with the rectum into the hollow of the sacrum, leaving a great space behind the pubis shut off from the perineum by the layer of recto-vesical fascia which forms the posterior layer of the sheath of the prostate. (See Fig. 2.) Into this space a great quantity of blood and urine

can be extravasated without passing into the scrotum or perineum.

Although in my experience the compression which caused the injuries of the pelvis and urethra has been generally lateral, it is possible that rupture of the urethra may also occur when the force of the injury has been directed from before backwards. In one case in which the nature of the accident rendered it uncertain in which direction the pelvis was actually compressed (the man was crushed under falling brickwork), the urethra was torn completely across in the usual position—viz., immediately in front of the prostate. At the post-mortem examination it was noted that the triangular and sub-pubic ligaments, though completely detached from the pubic arch, remained in connexion with the fascia lata of the thighs. The right pubis was unbroken, the left broken at each ramus. It is possible that the broken pubis and the bladder were pressed violently backwards by the blow, while the triangular ligament was prevented from accompanying them by attachments to the fascia lata of the thighs. The effect of this would be to snap the urethra just behind (or above) the triangular ligament. Although this is a possible explanation of the conditions actually found, the latter might even more probably have been caused by lateral instead of antero-posterior compression in the manner already described.

The occurrence of ruptured urethra in cases of fractured pelvis caused unequivocally by antero-posterior compression has not come under my own notice. It is mentioned in Bergmann's "System of Surgery" on the authority of several writers, but no particulars are given. Since I first pointed out and described the peculiarities of intrapelvic rupture of the urethra several writers have confirmed my observations and recorded similar cases, though different explanations have been suggested as to the manner in which the injury is caused. In 1901 Mr. O. J. Bond² of Leicester, in a paper on the treatment of cases of fractured pelvis with ruptured bladder or urethra, remarks: "There is the tender board-like, dull area above the pubes spreading laterally to the groins, which is due to the extravasation of blood and, in the case of injury to the bladder, the addition of extravasated urine in the prevesical space." He goes on to say: "In my experience the urethra gets injured where after the fall the crush comes with the patient lying on his side, thus driving the fractured sides of the pubic arch together like the blades of a pair of scissors and injuring or completely dividing the urethra in its membranous portion, just in front of the apex of the prostate. On the other hand, where the pelvis is crushed from before back the urethra is more likely to escape."

In 1902,³ a case, a boy, aged seven years, was admitted to St. Mary's Hospital under the care of Mr. Edmund Owen suffering from an injury caused by a pile of coffin lids which had fallen on him. Both tibiae were fractured, and there were marks of severe bruising over the lower part of the abdomen. An incision was made above the pubis and extravasated blood and urine were found in the prevesical space. The bladder was full of urine and not ruptured. "Inasmuch," says the report, "as no instrument could be passed into the bladder whilst there was escape of urine into the pelvis (*but not into the perineum*), there could be no doubt but the rupture was behind the triangular ligament." "Had the neck of the bladder itself been torn the bladder would probably not have remained full of urine under pressure. The rent, therefore, must have been between the neck of the bladder and the triangular ligament." No mention is made in any part of the report as to whether there was a fracture of any part of the pelvis.

A case very similar to this came under my own care in 1902. A boy, aged 14 years, while working in a coal mine was crushed between two tubs. The squeeze compressed the pelvis laterally. He walked home with help. About ten minutes after the accident blood began to come from the penis and continued to do so slightly all day. Three hours after the accident he passed urine free from blood with considerable pain. He was sent to hospital and on admission a few hours after the accident there were noted blood oozing from the penis, tenderness in the perineum, and a dull swelling above the pubis. A soft rubber catheter drew off a few ounces of urine, part bloody, part quite clear. An incision was made in the perineum, the skin of which was ecchymosed, and the urethra was found ruptured behind

the triangular ligament. It was evident that the urethra had not passed into the bladder but merely into a space between the pubis and the neck of the bladder. The latter was felt distended to halfway between the pubis and umbilicus. The distal end of the ruptured urethra could not be found. An incision above the pubis showed that the bladder was intact and distended. It was opened and a large quantity of clear urine escaped from it. A soft rubber catheter was passed backwards through the bladder, the perineal wound, and afterwards through the neck of the urethra and penis, being finally fixed in place by a suture through the frenum preputii. Further examination through the perineal wound showed that the urethra was not quite complete on the dorsal aspect. Examination showed no sign of any fracture of the pubic arch or any part of the pelvis. The bladder and the pubic wound were completely sutured and sealed by collodion. The perineum also was sutured with the exception of a small space behind for a drainage-tube. The bladder was continuously drained by Cathcart's apparatus attached to the catheter for nine days. Both wounds healed by primam, and one year later there was no stricture or urinary trouble.

In this case the anatomical findings were exactly similar to those of Mr. Owen's case. In both the rupture was typical intrapelvic rupture just behind the triangular ligament, and in both the extravasation of blood was in the pelvic and not perineal. In both the bladder itself was intact. In my own case two additional facts were noted: the compression of the pelvis was lateral (not antero-posterior) and the pubic arch was certainly not fractured. It was carefully examined during the operation. This disposes of the explanation sometimes offered of the rupture, namely, that it is caused by the direct approximation of the sides of the broken pubic arch cutting the urethra between the blades of a shears—the explanation adopted by Mr. Bond. It is significant that both cases were children, whom it is probable that a much greater deformation of pelvis may occur without fracture, and strongly supports the view put forward above that the rupture of the urethra is due to a violent stretching of the soft parts in the midsagittal plane.

In 1904 Dr. Henry Rutherford⁴ published a paper on ruptured urethra in which the following case is described: "A fracture through the body of the pubis close to the symphysis, and there was complete division of the urethra close in front of the prostate."

In 1905 Dr. David Lawson⁵ of Hull, in reporting a case of intrapelvic extravasation of urine, describes with great clearness the position of ordinary ruptures of the urethra in the perineum and the course which the extravasation takes in this injury. He then contrasts it with a case in which a gentleman was thrown from his horse and the horse fell on top of him. There was no swelling or sign of extravasation in the perineum or scrotum but a large dull tumour above the pubis reaching three parts up to the umbilicus. This was found to consist of blood mixed with urine lying in front of a full unruptured bladder. Careful palpation detected fracture of the ischial or pubic ramus. Dr. Lawson suggests that "the perineum came in violent collision with the projecting earth and that the floor of the pelvis with the bladder was driven up into the abdomen; that the recto-vesical ligament and all the soft structures were violently torn off the bone and forced up into the abdomen and that at the same time the pubic vessels were torn across and the urethra completely severed just at the tip of the prostate behind the deep layer of the triangular ligament. Against this explanation seems to militate the absence of bruising of the perineum which one would expect from a violent blow. It seems to me more probable that the case was really one of lateral compression of the pelvis, the mechanism of which has been explained above."

The cases which I have quoted confirm in almost every particular the description of intra-pelvic rupture of the urethra which I described in 1894, although, so far as I am aware, my observations were not known to any of the authors of them. The testimony to the accuracy of my description in each case quite independent is the more striking and valuable.

Various methods of treatment have been adopted:

⁴ THE LANCET, Sept. 10th, 1904, p. 751.

⁵ THE LANCET, March 25th, 1905, p. 790.

² THE LANCET, Nov. 23rd, 1901, p. 1404.

³ THE LANCET, Feb. 15th, 1902, p. 443.

recommended for dealing with rupture of the urethra complicating fractures and injuries of the pelvis. The earlier writers recommend first to try to introduce a catheter into bladder and if this succeeds to leave it as long as circumstances permit. As a matter of fact, this course is not practicable, for when the rupture is complete it is not impossible to reach the bladder by simple catheterism, the ends of the torn urethra being separated by a considerable interval. If successful at all it can only be achieved by a rigid instrument which is unsuitable for continuous drainage of the bladder. What often happens when the catheter is passed is that it enters the prevesical space and it draws off several ounces of extravasated urine which collects in that position, and as the point of the catheter is to lie in a free space the bladder is thought to have been successfully entered when in reality it lies full of urine and the catheter. I have committed this error myself seen it done several times by others. The importance of knowing this possibility is obvious. When the attempt to empty the bladder by means of the catheter has been made without success, the next step formerly advised was to make an incision in the perineum and attempt to reach the bladder by that route. If it fails, extravasated urine will find its way out through the perineal wound and further chief will be prevented.

Dr. Bond, whose paper I have already quoted and who recognises clearly the position of the rupture in the urethra, recommends adding a suprapubic incision to the perineal and in some cases advises opening the bladder suprapubically and inserting a drainage tube through the neck of the bladder and at the perineal wounds. Dr. Rutherford* also advises combined suprapubic and perineal drainage, together with use of a soft catheter passed along the whole course of urethra. Dr. Lawson† adopted a similar procedure in case with good result. My own practice is to rely entirely on continuous drainage of the bladder through a rubber catheter passing along the whole length of the urethra into bladder and attached to Cathcart's suction apparatus, advantages of draining the bladder by the natural route being obvious. In the first place, it approximates the torn ends of the ruptured tube and permits union and repair to take place under the most favourable and most rapid conditions. In the second, it is possible by this means to keep bladder continuously empty without the escape of any urine into the wound. Cathcart's apparatus is by no means stiff when attached to a tube introduced into the bladder through a suprapubic incision, because it is almost impossible to prevent the entry of air into the tube, and this greatly aids its powers of suction. But when the same apparatus is applied to a catheter introduced through the urethra this difficulty does not occur and I have found it perfectly able.

It may be said that, granting the advantage of draining the bladder through a catheter in the urethra, it is not always possible to introduce it. I believe that if the tomy of the injury is correctly appreciated there will not be any difficulty in finding the distal end of the torn urethra through a perineal incision, which should always be the first step in dealing with these cases. I have mentioned that the bladder and prostate after the rupture, when complete, fall back on the rectum into the hollow of the sacrum, palpation through the rectum it is easy to identify the state and then to bring it into the perineal wound, where the orifice of the urethra is easily seen. In the case of my patient mentioned above the rupture was not complete, and the patient not having reached puberty the prostate was not yet felt. I therefore opened the bladder above the pubes, as done also by Dr. Lawson* in his case, and passed the catheter from behind forwards. By this means if necessary a catheter can always be introduced through the whole course of the urethra. It will be noted that in the case of the alluded to I completely closed the bladder in order to secure the success of the suction through the catheter. Draining of both wounds was primary and the whole consequence was rapid and complete. A subsequent case of complete rupture with fractured pelvis treated by the same method, but without a suprapubic cystostomy, was equally satisfactory and normal micturition was resumed in three weeks.

The question of suturing the torn urethra depends on circumstances. When the rupture is complete and the torn ends widely separated sutures should certainly be employed.

In the first place, the obvious thing to do to repair a gaping wound is to sew it up and so promote direct healing and diminish the chance of stricture. In the second place, it is important to retain the torn ends firmly together in case it may be necessary to change the catheter. When the urethra is held together by strong supporting sutures of silkworm gut (not passing through the mucous membrane) the catheter may be removed at the end of a week or earlier if necessary and a fresh rubber catheter introduced quite easily. When the rupture is not complete and the torn ends fall naturally together the sutures may be dispensed with.

The chief objection likely to be raised to the method I have recommended is the danger of closing a large wound which is liable to become septic. Sepsis is indeed a danger of all wounds and in urinary surgery it is peculiarly dangerous. Drainage of the pelvic wound should therefore always be provided for by tubes or gauze wicks for the first 48 hours, or longer if necessary. Sepsis can be prevented in the great majority of cases if the same scrupulous care is exercised in urinary as in all other cases. The chief risk is that infection has already occurred before the case comes under the surgeon's care, either by neglect or by the introduction of a catheter without proper precautions. In a case in which the history and symptoms make an injury of the bladder or urethra probable it would be well if house surgeons or others who are first called would refrain from passing dubious instruments and leave all manipulations to be done in the operating-theatre under proper conditions. Apart from previous infection all the conditions are favourable for aseptic healing. The patients are generally healthy and young, with normal urine, which opposes no bar to primary union even if it comes for a short time in contact with the wound.

Lastly, a few words may be added on the treatment of rupture of the urethra due to direct violence in the perineum, such as kicks and straddling falls. The guiding principles are exactly the same. Avoid infection by careless catheterisation and cut down at once in the perineum whenever the passage of blood from the penis makes it certain that the urethra has been wounded. Even contusions and partial mucous lacerations are apt to be followed by stricture if not incised, drained, and where necessary repaired by sutures. When the rupture is in the membranous part, it is, as I have already pointed out, in front of the triangular ligament and in this position the rupture is easily found even when it is complete. A soft catheter should be passed into the bladder and the two ends of the urethra brought together over it by means of sutures just missing the mucous membrane. The perineal wound is then closed with the exception of a small portion drained by a gauze wick, and if the urine be drained by Cathcart's apparatus for a week, primary union of the urethra without stricture is not difficult to obtain. The method of merely passing a catheter and tying it in always leads to sepsis and is no bar whatever to the production of stricture. The method is faulty and dangerous and should be entirely abandoned.

Note.—I have omitted to refer to another published case which illustrates very clearly the difference between pelvic and perineal ruptures of the urethra—namely, "A Case of Fatal Pelvic Injury in a Child in which a Collection of Blood in the Prevesical Space simulated Distension of the Bladder," by Mr. Herbert Page,‡

Wolverhampton.

GALL-STONES IN THE APPENDIX.

By H. A. LEDIARD, M.D. EDIN., F.R.C.S. ENG.,
SURGEON TO THE CUMBERLAND INFIRMARY.

A MAN, aged 26 years, was admitted to the Cumberland Infirmary in April, 1906, complaining of having had two attacks of abdominal pain, diagnosed as appendicitis. The patient was very healthy up to two or three years ago, when he began to suffer occasionally from slight abdominal pain and discomfort after taking food and at times a feeling of weariness or actual pain in the lumbar region after any exertion. Two years before admission he was operated upon for inguinal hernia in this infirmary. The patient as a rule had been rather constipated and was especially so about four months before admission; for some weeks at this time he noticed that his urine was of a dark reddish colour on

* Loc. cit.

† Loc. cit.

‡ Loc. cit.

standing. About a month before admission the patient had an attack of acute pain over the whole lower abdomen lasting one day. He vomited once then and had to keep to bed all day. On the next day, although he felt some slight abdominal pain and was rather weak, he went back to work again. His urine at this time was again thick and dark red in colour. He remained fairly well for a month and then seven days before admission acute abdominal pain began, mostly about the umbilicus, but later becoming more marked in the right iliac region. There were frequent vomiting for the first day, severe headache, and constipation, while tenderness and slight resistance were found over the appendix region. The pain gradually lessened and vomiting ceased, until in four days he was able to get up and on admission, three days later, there was no pain or tenderness and he was quite able to go about. At no time had the patient had pain over the liver region, in the chest or about the shoulders, nothing ever suggesting gall-stone colic, nor had jaundice or even the slightest yellow tinging of the skin or conjunctiva been noticed either by the patient or his friends. No gall-stones had ever been seen in the motions.

The abdomen was opened in the right iliac region and the appendix was exposed. Slight adhesion of the appendix to the posterior abdominal wall at one point was found: the appendix was long and had rather thickened walls. The mesentery was tied and the appendix was removed. It was found to contain some turbid mucus and 11 small stones, of varying sizes from that of a pea to that of a large pin-head. These stones were black in colour, rather soft, and faceted like gall-stones. On examination they were found to consist of cholesterin and to contain bile pigment. The patient made a good recovery and was discharged in about three weeks. For the clinical notes I am indebted to Dr. William Templeton, house surgeon in the hospital at the time.

Remarks.—The occasional presence of gall-stones in the appendix is fully established and is alluded to in general terms by modern writers of text-books. Roberts,¹ for example, remarks "that they cause trouble by lodging in the vermiform appendix." As far back as 1871 it was a recognised fact that gall-stones were liable to be arrested in the appendix,² but Murchison, in writing on the same subject, expressed a doubt if the concretions were not intestinal rather than biliary.³ That the occurrence is not exactly frequent may be gathered from Naunyn who in 1892 wrote:⁴ "It has happened that a gall-stone has made its way into the vermiform appendix, the result of which accident may be perityphlitis and fatal peritonitis." Naunyn mentions Budd's case, quoted also by Murchison, in which a gall-stone in the vermiform appendix caused perforation and fatal peritonitis. The same author mentions cases of a similar kind by Trousseau, Sirey, Rehn, Treves, and Wegeler. In Wegeler's case the supposed gall-stone was by chemical analysis proved to consist of faecal matter. Mistakes of this kind might easily arise if the appearance only of the concretion was relied upon; if, however, a concretion was faceted and had a chink-like sound when allowed to fall on a hard surface such as a marble slab, it would probably be a gall-stone, but chemical analysis will always remain as the true test to determine the source of a concretion in the appendix.

As a general rule the size of stones met with in the gall-bladder or separated from faecal discharge is too large to enter the canal of the appendix, and the same is true for the stones of fruit, formerly supposed to get into the appendix; the stercolith having simulated an orange pip or a damson stone. Here again a chemical analysis would effectually serve to get rid of a fiction which has been repeated in all books and is still believed in by some. What I suggest is that all concretions found in or near the appendix, or in an abscess or otherwise, should be systematically examined by section and by analysis in order to settle definitely whether a concretion is a stercolith or a gall-stone, covered or not by faecal deposit. On one occasion a hair was imbedded in a stercolith from an operation I performed lately, and a similar experience fell to Mr. W. H. Battle.⁵ The hair was possibly the nucleus on which the concretion formed, and in the

same way a gall-stone or some other foreign body might become a nucleus. Treves⁶ has written that mischief in the appendix may be due to a foreign body, such as a pin, a grape pip, a small shot, a piece of bone, and the like. "Most of the so-called cherry-stones," he writes, "and gall-stones found in the appendix are calcareous concretions mixed with faecal matter."

A good example of faecal calculus was removed lately in the course of an appendix operation; it shows that a seed has formed the nucleus and around it are layers of inspissated faeces and the whole is impregnated with lime salts. By the courtesy of Mr. D. Prain, director of the Royal Botanic Gardens, Kew, this concretion was examined by Mr. L. A. Boodle, F.L.S., assistant in the Jodrell Laboratory in the garden. The nucleus was compared with practically all the objects that might conceivably be met with in such a situation—grape or raisin, gooseberry, currant, and other small seeds of fruits generally consumed—but it did not agree in the least with any of them. But with the fruitlet, or "pip," of a fig it agreed so absolutely in size, general appearance, and structure that, in the opinion of Mr. Boodle, the nucleus of my concretion could be accepted with hardly any hesitation as coming from the fig.

Concretions can sometimes be felt in the appendix through the abdominal wall without the aid of an anæsthetic, the favourable condition being a relaxed state of the muscles and a moderately thin paries. In the case recorded these gall-stones were actually felt, not all but some, and in consequence of the presence of concretions the operation was done, although the condition of the patient seemed absolutely healthy. There cannot be much doubt that these gall-stones would have perforated sooner or later.

The pathological association of gall-stones in the gall-bladder and appendicitis, to which attention has been drawn, is hardly an established doctrine and may be merely a coincidence, although 35 per cent. of Ochsner's patients operated on for gall-stones had suffered from appendicitis.⁷ Strange indeed it would be if destructive lesions in the appendix by infecting the blood in the portal system were among the causes of the formation of gall-stones and that gall-stones might find their visit a return one to the appendix. The whole question is dealt with by Moynihan. A death from perforation of the appendix by a gall-stone is recorded by Mayo Robson in THE LANCET of Dec. 29th, 1906, p. 1768.

Carlisle.

PNEUMOTHORAX FROM PUNCTURE OF THE PLEURA.

By J. C. F. D. VAUGHAN, M.R.C.S. ENG.,
L.R.C.P. LOND.,

LATE HOUSE SURGEON, ST. THOMAS'S HOSPITAL AND EAST LONDON
HOSPITAL FOR CHILDREN.

As pneumothorax is an uncommon condition and stab wounds are, fortunately, also not common, at least, in England, I thought the following case might be of interest. I was at the time surgeon on a well-known line to the East and the vessel under my charge was running down the Red Sea with a shade temperature of 104° F., when one evening the native barber (my interpreter and go-between with the native crew) came and reported that one coolie (lascar sailor) had stabbed another in the back with a clasp knife having a three-inch blade. It was then about 8.30 o'clock on the evening of July 21st, and on walking aft I found a well-built lascar, about 24 years of age, with a terrified face lying in a pool of blood surrounded by a curious ring of squatting natives.

On examination the patient had an anxious expression, his respirations being very rapid, shallow, and thoracic in nature, his chest being in a position of full inspiration, especially on the left side, which looked almost blown up. There was a clean-cut incised wound three-quarters of an inch long in the back between the eighth and ninth rib and two and a half inches from the mid-line, which was perfectly clean and had stopped bleeding, the loss of blood having been unimportant. There was no surgical emphysema. The pulse was rather feeble and rapid, the patient evidently

suffering from shock but not to a severe degree. The apex beat of the heart could not be detected but the cardiac dulness was considerably diminished in area and displaced towards the right side, the dulness beginning at the left edge of the sternum above, about the fifth rib, and stretching to the left to a point two and a half inches internal to the nipple line, while on the right it reached some little distance to the right of the sternum. The liver dulness could not be satisfactorily made out and this organ could not be felt owing to the patient holding his abdomen extremely rigid. The percussion note over the whole left chest was more resonant than on the opposite side, but the hyper-resonance was not very pronounced. On auscultation the heart sounds were faint but normal, the maximum apex beat being two and a half inches internal to the nipple line, agreeing with the percussion dulness. The breath sounds were almost absent over the left chest; there were no adventitious sounds. Cough sound was not tried, neither was succussion sound. There was no expectoration nor hæmoptysis and but very little pain. The diagnosis of partial pneumothorax was made and also probable penetration of the lung. The wound was cleaned up and dressed but was left unprobed, while the patient was ordered to remain still under the watchful care of the almost panic-stricken barber, and instruments were got ready in case the wound either in the lung or parietal pleura should act as a valve and render an immediate operation necessary, and finally, an electric cargo lamp was swung overhead. The patient's condition improved during the night and he slept fairly well, the breathing becoming less shallow and the symptoms of shock passing off.

On the following day the patient seemed fairly comfortable but complained of pain in the left side of the abdomen just beyond the end of the eighth rib. The left chest was resonant except at the back in the wound area where possibly there was some dulness. The breath sounds on the same side were extremely faint, being practically absent. The temperature was 99°. On the 23rd he spat blood two or three times during the morning, but his condition was good and he was quite comfortable except for the pain in the left side of the epigastrium, which was not at all severe but was increased by coughing or a "big speech." The temperature was 99°. Heart dulness began above between the third and fourth rib, the apex beat and left limit of cardiac dulness being one inch internal to the nipple line, while it did not extend to the right of the sternum. The liver dulness was normal and the liver could not be felt, though the abdomen was flaccid. Resonance and breath sounds were normal; there were no adventitious sounds or dulness. On the 24th no blood-spitting had occurred since 1 P.M. the previous day. The patient had no cough but felt comfortable and well, only having slight pain in the left epigastrium on deep inspiration or changing his position. The thorax was quite normal except that behind at the left base the breath sounds were fainter than on the opposite side, but the resonance was equal. The temperature was 98.4°. The tongue was clean and the abdomen was soft. The man was moved into his quarters on account of the South-West Monsoon. On the 25th and 26th his temperature was 99° but he was otherwise well.

On July 27th the coalsie was discovered sitting up quite normal in all respects, though he complained of pain on the previous night. On the 28th there was still a little pain. On the 29th the patient was very well and happy, complaining of pain for the last time. The breath sounds at the left base behind were harsher and more audible than on the right side. Other signs were normal. The wound had healed by first intention. On the 31st he commenced walking about but had anaesthesia in the left epigastrium beyond the end of the eighth rib about two inches by three inches in extent. On August 3rd the chest was normal in all respects but the anaesthesia continued. The patient was seen up to August 5th, when having reached port he went ashore and was lost sight of.

I consider the chief point of interest about the case is its affording another proof of the rapidity with which air can be absorbed from the pleural cavity. As regards the damaged, if not severed, while with respect to the changes at the left base it is difficult to say to what they were due, but a possible explanation is that there was at first an inflammatory exudate giving slight dulness and afterwards diminished breath sounds, even when the note was not impaired; then absorption took place and also some fibrosis of

the wounded lung, which thus became a better conductor of sound and caused harsher breath sounds. No doubt there are other points that might have been noticed but I must plead the difficulties to which a ship's surgeon is subjected: he cannot speak the language, is helped in all small matters only by an incompetent barber, and last, but not least, has to contend against the noise of the engines, steam steering gear, and South-West Monsoon.

Ashburton, Devon.

A SUGGESTION FOR THE TREATMENT OF CASES OF CHRONIC SCIATICA AND SIMILAR FORMS OF NEURITIS.

BY J. CURTIS WEBB, M.A., M.B., B.O. CANTAB.

CERTAIN cases of sciatica, or indeed of any form of neuritis, are at times of so obstinate a nature as to be the despair of the unfortunate sufferer as well as of the one or the many medical men from whom alleviation is sought. Some cases are slight and yield easily to treatment but in a large number remedy after remedy is tried in vain, till at last the disease may seem to exhaust itself and leave the patient worn out by pain, with more or less stiffness in the limbs, and the retrospect of months wasted in invalidism and of a purse much lightened by fruitless searches after relief. In many cases, too, even if the trouble be not continuous, it may disappear, only to recur again at shorter or longer intervals with equal or even increased severity till the unfortunate patient feels that his nerve is like a volcano constantly on the verge of an eruption and liable to break out on the smallest stimulus. Having for some long time past been using static electrical treatment for a variety of diseases, and having had some remarkably successful results in several most obstinate and chronic cases of sciatica, I am anxious to bring this remedy more prominently before the profession. And here let me mention for the benefit of those who are ignorant of this form of electricity that it differs radically from currents derived from battery or dynamo on the one hand—whether continuous faradic, sinusoidal, or polyphase—and from "high-frequency" currents on the other. Its voltage is enormous, its ampérage infinitesimal, and its frequency of pulsation (for it is not alternating in ordinary circumstances) anything that the operator wills. It is unnecessary here to say more than that I employ for the class of case under discussion the Morton wave current, the brush, and indirect sparks. Those who possess static machines will know the modalities I refer to; those who do not would find a long dissertation on influence machines and their methods of use wearisome and useless. The important point at the moment is the *result* of the treatment, specially as it applies to sciatica or other forms of neuritis. Let me briefly mention a few cases.

CASE 1.—An officer in the army, aged 40 years, got his first attack of right-sided sciatica in Cashmir in November, 1895. The pain extended from the notch to the heel. While his pain was not so severe as to cause him to be invalidated for any length of time it always came on if he got over-tired or much worried, and at times would quite cripple him. When he came to me in October, 1904, he had had a severe attack since August. He could hardly walk, and sitting was accompanied by great pain in the sciatic notch. He had static treatment and no other remedies for about four weeks, when he went away quite free from pain or stiffness. In December, 1905, he wrote me that he "had a slight reminder of it in January which lasted less than 24 hours and since then has had absolutely no return of the sciatica at all." I saw him a few days ago and he is still quite free. Considering that since November, 1904, he has been engaged in work in Ireland necessitating long bicycle and jaunting-car rides in all weathers and sleeping in wayside inns and that he has also had a great deal of brain work and worry I think one may regard his cure as fairly established, though the malady had lasted nine years. There is no stiffness whatsoever left.

CASE 2.—A man, aged 59 years, has always had a tendency to sciatica in both legs. It was sometimes severe, sometimes slight, but he was always liable to attacks on the slightest provocation. When I saw him in June, 1905, he had been suffering rather severely in the left leg, so I put him on static treatment. He only had six applications when he was quite

free from pain and in May, 1906, he told me he had had no sciatica all the winter in the limb I had treated though he had had it in the nerve of the opposite side to a slight degree.

CASE 3.—In December, 1905, a man, aged 53 years, came to me from Herefordshire. He had been suffering from sciatica in the left leg since early in the preceding August. Prior to my seeing him he had been to Droitwich, where he had 32 brine baths with massage and "battery." He was no better and after being at home for ten days he went to Bath and had dowsing radiant heat and daily applications of the "battery." After this he came to town to consult a nerve specialist who advised rest in bed for a fortnight and a mixture. This treatment he continued for five weeks without much benefit. He was at the same time taking sulphate baths and having mustard leaves applied over the nerve. Although when he came for treatment he stayed at a hotel within five minutes' walk of my house he was compelled to come round in a four-wheeler, into, and out of, which he always had to be helped. He commenced the applications on Dec. 12th and came twice a day and returned home on the 27th cured, save for a little stiffness. I should add that, in addition to the static treatment, the patient had a few applications of the x rays and some concentrated arc light along the line of the nerve. As the stiffness still persisted he returned in February, 1906, and had six treatments when the stiffness left him. In June his wife reported that he was perfectly well as far as his sciatica was concerned, though he did occasionally have general gouty sensations all over, but never any tendency to a return of his old symptoms, and on Nov. 1st he wrote that he still remained free from pain and could walk well without any limp.

CASE 4.—This is a peculiarly interesting case, as the patient, aged 29 years, was, at the time of his first attack two and a half years ago, house physician at one of the largest London teaching hospitals. The attack was so acute that he was "warded," and was therefore in a position to have the very best advice and treatment. He was in hospital for three weeks and then went to Buxton for three weeks and later to Aix-les-Bains for nearly two months. He got somewhat better and took up his appointment in November, 1904, and worked for five months, but always in some pain, and used to take aspirin and receive electric baths and applications in the special department of the hospital. He then had another acute attack and from that time till I saw him in July, 1906, he had tried almost every form of treatment. He had been to Bath for two months, where he was on a sofa nearly all his time with such severe pain that he had to use morphine hypodermically. He had had three weeks at Droitwich and a month at Salsomaggiore. The nerve had twice been stretched by the closed method. He had had dowsing light treatment, radiator light, massage, high-frequency, and De Watteville current applications—in fact, everything that money could procure or the united talent of his hospital staff could suggest had been given a trial. When he first came to me the pain was so bad on standing or walking that he could take no exercise and was quite unable to follow his hospital work. He has had a total of 72 static treatments and is now able to play two rounds of golf a day without feeling his leg unless he gets very tired; he can spend hours going round the wards of the hospital or standing watching operations; and he can play tennis and is just now taking up a resident appointment at another large metropolitan hospital. His progress was slow at first. He began treatment on July 26th and ceased temporarily on August 11th, when he was better, but far from cured. I went away for my holiday and he proceeded north. On Sept. 8th he wrote me: "It is high time I reported the marked improvement I have made. I can play occasional sets of tennis, and one afternoon I played three rather long ones in complete comfort—a fourth rather stirred up the sciatica again, but I felt none the worse for it next day. I still feel the indefinite pain hanging about, always varying a little, but still I am very pleased to be able to do as much as I can, and am in great hopes that another dose of static electricity may effect a cure." I mention this point as I wish to draw attention to a fact about electro-static treatment—viz., that very often one seems to be only making slight progress during a course of applications, but that if one stops for a time the improvement goes on steadily. In many instances the treatment aggravates the symptoms at first, which I always regard as a good sign, inasmuch as in

my experience I find that it indicates that the trouble is not too chronic for improvement to be hoped for. Oct. 1st treatment was recommenced and ceased Oct. 22nd, he being apparently cured. Of course, this has not yet stood the test of time, but, judging from previous results, I see no reason why, with ordinary care the patient should relapse. He is to-day quite free of pain and able to do all the work of his hospital appointment. I have purposely not touched on any of the early static or other forms of neuritis that I have treated. I find invariably, if the patient be not too advanced in years, can effect a rapid cure in these cases if one can get it right from the onset. All forms of neuritis or neuralgia provided they are not due to pressure of tumours or of irremovable cause, are among the most satisfactory of many cases that can be cured or relieved by this potent therapeutic agent.

Bina-gardens, S.W.

A CASE OF INFLUENZAL MENINGITIS

By J. SHOLTO U. DOUGLAS, B.A., B.M., B.Ch. Oxo
DEMONSTRATOR IN PATHOLOGY AND ASSISTANT CURATOR OF THE
MUSEUM, ST. GEORGE'S HOSPITAL; AND RAULIFFE
TRAVELLING FELLOW IN THE UNIVERSITY
OF OXFORD.

ALTHOUGH cases of meningitis occurring during, following immediately upon, an attack of influenza have from time to time been reported in this country, the number of instances in which Pfeiffer's bacillus has been recognised in the cerebro-spinal fluid or in the meningitic exudate is not numerous. It seems, however, that it is much more common to find this bacillus in such situation accompanied by other organisms than to find it in a pure state. Althaus,¹ in his monograph on influenza, mentions that several observers had seen meningitis and meningo-myelitis in consequence of an attack of this disorder. Weichselbaum quotes Pfäfl² as being the first to show that Pfeiffer's bacillus could be found in the exudate of certain cases of meningitis and also gives references to the work of several other observers. P. M. F. Stéphane Dubois³ at a later date collected 11 examples of meningitis in which the bacillus influenzae was present, a post-mortem examination having been made in the case of nine, whilst in the remaining two the organism was found during the life of the patient. He deals in a very thorough manner with these cases, concluding, as also does Weichselbaum, that the meningitis is generally secondary to affection of the naso-pharynx and adjoining sinuses, more rarely to middle ear disease, occurring in consequence of a pre-existing, and more usual type of influenza.

Besides the cases collected by Weichselbaum and Dubois other examples of meningitis, in which Pfeiffer's bacillus was present in the exudate, have been described by Thomae⁴ and Graefski,⁵ by Mya⁶ (three cases), and in this country by Nuthall and Hunter⁷ (three cases), and by Bury.⁸ Nuthall and Hunter found a bacillus which, morphologically and in staining properties, resembled the bacillus of Pfeiffer, mingled with pathogenic cocci in three out of ten cases of cerebro-spinal meningitis examined by them with bacteriological methods. They mention that a similar organism had been demonstrated by Nauwerck, Högarstedt, and Leichtenstern, and state that Slawych⁹ and Lander¹⁰ had recorded undoubted instances of a meningitis caused by the bacillus influenzae. Bury brought forward Dreschfeld's case in which the necropsy was performed by Moore who found in the exudate, in sections stained with dilute carbol-fuchsin, bacilli resembling those of Pfeiffer and mentions some other cases which are also quoted in the papers mentioned above.

The introduction of the examination of the cerebro-spinal fluid withdrawn by lumbar puncture to clinical methods has given us a chance of determining the presence of the micro-organism responsible for a cerebro-spinal meningitis during the life of the patient and so of placing the diagnosis of the condition on a sounder basis. It is to be hoped that this will lead to the identification of the influenza bacillus in certain cases of meningitis, even though the patient recovers from the attack. For contamination of an organism quickly occurs after death, as is well shown in the case recorded below.

The patient, a female infant, aged ten months, was admitted into St. George's Hospital under Dr. H. D. Rolleston's care on March 22nd, 1906, with a two days' history of rigidity, general pains, and irritability. No tuberculosis, rheumatism, or fits occurred in the family history, the patient being one of six children, all of whom were healthy. The child was born at full time by normal labour, was fed on cow's milk, and had had no previous illness. During the two days previous to admission the patient had had several attacks of rigidity and general pain on movement but slept well—occasionally screaming during sleep. On the day previous to admission the child vomited three times. She had no cough, fits, or diarrhoea.

On admission the infant was well nourished and was lying in bed on her right side giving vent, about every half hour, to occasional screams. The anterior fontanelle was patent, pulsating, and presented a slightly increased tension on palpation. No squint, inequality of pupils, or paralysis of the ocular muscles was observed and the discs were clear. The tongue was moist and clean, while the heart and lungs were normal. The abdomen was slightly distended and tympanitic. There were no enlargement of the spleen, no ascites, and no sweating. As regards the nervous system, all the cranial nerves were normal and the retinal discs were clear. There were no muscular wasting and no obvious loss of power in the muscles, all of which presented good tonus. Kernig's sign was present and slight rigidity of the neck muscles, but no obvious head retraction. Sensation was apparently normal. All deep reflexes were increased, but no clonus could be elicited. The abdominal and epigastric reflexes were absent, while the plantar reflex was of the extensor type. At this time the temperature was 101.2°F ., the pulse was 136, and the respirations were 48 per minute.

On March 26th the child had become semi-comatose and exhibited a squint owing to paralysis of both external recti muscles. The ocular discs remained clear and occasional twitching of the levator anguli oris was noticeable together with slight weakness on the left side of the face. The abdomen was less distended, while the anterior fontanelle was bulging more, but still pulsated. Nasal feeding had become necessary. Lumbar puncture was performed, five cubic centimetres of fluid being withdrawn. This contained many polymorphonuclear leucocytes, much albumin, and was yellowish in colour. Examination of the cerebro-spinal fluid showed that the freezing point gave $\Delta = -0.75^{\circ}$ and that sodium chloride was present up to 0.78 per cent. In the fluid were many feebly staining fine, short bacilli, which culturally and microscopically corresponded with the influenza bacillus.

On March 27th the child entered a series of spasmodic states, commencing at 6 A.M. During these all the limbs were extended with rotation inwards of the forearm with fingers adducted and thumb flexed across the palm. The feet were inverted and the toes were hyperflexed. The spasms were tonic in character and persisted about half a minute, the limb spasm being accompanied by marked opisthotonos and bilateral contraction of the abdominal muscles. The hyperextended limbs were strongly adducted and the eyes were rolled upwards. The face did not appear to participate in the spasms. The onset of such a spasm was heralded by 10 or 12 deep inspirations, but during the attack the chest was fixed in the expiratory position. Except five minutes, the child lay motionless and did not respond to stimuli. The anterior fontanelle was still bulging, and the illness the pulse-rate was increased, varying between 124 (minimum) and 144 (maximum). The temperature was raised, varying slightly about 102° , but fell to normal on the morning preceding death (March 27th) and throughout that day gradually rose to 104.8° at 10 P.M. The respiratory rate varied between 48 and 32.

Necropsy.—I made a thorough post-mortem examination 12½ hours after death and found the body to be well

nourished and all the thoracic and abdominal organs healthy with the exception of the lungs, which were emphysematous throughout with scattered areas of collapse, the liver, which showed cloudy swelling, and the pancreas and kidneys, which were somewhat congested. The skull was healthy, but on removal of the vault a quantity of nearly clear fluid escaped. Both middle ears contained thick mucus but no pus. The brain was well developed but was much swollen and somewhat softened and its convolutions were flattened. Over the surface of the organ under the pia mater was a quantity of thick green pus which was distributed along the line of the blood-vessels, both over the vertex and the base. The upper aspect of the cerebral hemispheres were more especially attacked in the frontal region. Here the pus formed a continuous layer stretching over all the gyri which lie in front of the fissure of Rolando, which itself was almost obliterated by the septic process. Behind this fissure the sulci were glued up by the exudate, but the summits of the gyri were almost free of pus. Below, the fissure of Sylvius was occluded and the pus lay upon the posterior part of the gyrus rectus on each side. In front of the chiasma and over the anterior surfaces of the temporal lobes the pus was thickly accumulated. Behind this pus was present over the mesencephalon and pontine regions, spreading outwards over the under surface of the lateral lobes of the cerebellum. In this region there was rather more pus over the right than the left cerebellar lobe. The contiguous surfaces of the occipital cerebral lobes and the cerebellum appeared to have almost escaped, a few beads of pus being alone evident along some of the blood-vessels save over the culmen monticuli, where a marked accumulation was in evidence. The lateral ventricles did not appear distended nor did they contain pus. Slight congestion of the brain substance was evident on section. The inner surface of the cerebral hemispheres was covered with pus along the lines of the blood-vessels, whilst over the upper aspect of the corpus callosum was a marked accumulation. The pus did not seem to have penetrated into the depths of the fissures. The fornix and corpus callosum were softened and infiltrated with pus. Covering the posterior and lateral aspects of the spinal cord was a thick layer of pus extending throughout its length. In thickness the purulent material was nearly as great as the diameter of the cord. The anterior surface of the cord was free from inflammatory exudate. Histological examination of the purulent exudate confirmed the naked-eye appearances.

Dr. O. Slater examined the cerebro-spinal fluid obtained during life by lumbar puncture, but found no tubercle bacilli in stained smears. There were seen, however, many small weakly stained bacilli in specimens treated with methylene blue, which were of the shape and size of Pfeiffer's organism and were situated both intra- and extracellularly. They took the dye rather better when stained with carbol-thionin blue, but lost the stain when treated by Gram's method. Some of the fluid was inoculated on agar, serum, and broth. At the end of 48 hours there was no growth found, but on adding some sterile blood to these tubes a good growth of typical colonies of influenza bacilli was obtained in an uncontaminated condition. Dr. Slater further examined pus taken at the necropsy from the surface of the brain, some of the intraventricular fluid and some of the mucus from the middle ear. Smear preparations of each of these materials showed the same organisms. On agar the pus from the surface of the cerebrum gave a practically pure culture of Pfeiffer's bacillus, whilst the mucus from the middle ear and the cerebro-spinal fluid gave a good growth of influenza bacilli mingled with a sarcina flava and the bacillus coli communis. Similar results were seen on serum tubes inoculated with the same materials. The Pfeiffer's bacillus was further subcultured for some little time on blood agar. No animals were inoculated with the bacillus, as no sufficiently typical phenomena have been described in the case of animals injected with living cultures of the influenza organism to aid the diagnosis.

In examining the literature I have been unable to find any other case of meningitis due to Pfeiffer's bacillus reported in this country in which the organism has been obtained in culture both from the cerebro-spinal fluid during life and from the meningeal exudate after death.

In conclusion I should like to record my thanks to Dr. Rolleston for allowing me to publish the medical notes of the case recorded above, and to Dr. Slater, the director of the clinical laboratory, for permitting me to record his bacteriological investigations.

St. George's Hospital.

THE PERSISTENCY OF THE INFECTION IN CERTAIN CASES OF SCARLET FEVER.

By H. POOLE BERRY, M.B. LOND., M.R.C.S. ENG.,
MEDICAL OFFICER OF HEALTH OF THE BOROUGH OF GRANTHAM.

DURING the past 12 months we have been passing through an extensive epidemic of scarlet fever in the borough of Grantham. Our estimated population is 17,929 and the area of the borough (1677 acres) is sufficiently small to have enabled me to obtain a very close and intimate knowledge of the various relationships which have existed amongst the patients affected. I have been for 18 years medical officer of health of the borough and during all this time, although our methods of dealing with the infection of scarlet fever until recently have not been drastic, the patients being isolated as far as possible in their houses, previously to the present epidemic I have only known of one instance in which a "return" case occurred—that is to say, a fresh case occurring in the same house after the recovery and disinfection of the patient and the premises.

During the present epidemic 331 cases have been notified. We have isolated 217 cases in hospital and have employed a nurse to assist in the isolation and subsequent disinfection of those patients who remained at home. Indeed, all ordinary precautions were taken, but still the disease continued to spread, and after much careful investigation I came gradually to be sure that this was due to some means other than those generally accepted. In the light of recent investigation my attention was naturally drawn to the possibility of infection being conveyed by means of those patients who had apparently recovered, and I have been forced to the conclusion that the infection may in certain cases remain in the patient very much longer than has been generally supposed. According to my investigations there were 19 cases which, after apparently complete recovery and disinfection, gave rise to 23 other cases, and I have reason to suspect that not a few others were due to this cause. It is also evident that this persistency of infection was not confined to patients treated in hospital, for three at least of these "infecting" cases were treated at home. Comparing these results with my previous experience, it appears necessary to presume that this persistence of infectivity may exist in some epidemics and not in others. The following cases testify to my conclusions as previously expressed:—

Alfred P—, taken ill on Nov. 23th, 1905; treated at home. Sidney P—, admitted to hospital on March 2nd, 1906; discharged on April 23rd.

Florrie B—, taken ill on Nov. 25th, 1905; treated at home. Winifred B—, admitted to hospital on Jan. 17th, 1906; discharged on March 1st. Doris B—, admitted on Jan. 17th; discharged on Feb. 24th. Cecil B—, admitted on Jan. 23rd; discharged on March 28th.

Dorothy S—, admitted to hospital on Dec. 13th, 1905; discharged on Jan. 25th, 1906. Horace S—, admitted on Feb. 27th, 1906; discharged on April 18th.

Clecy C—, admitted to hospital on Dec. 14th, 1906; discharged on Jan. 31st, 1906. Clara C—, admitted on Feb. 4th, 1906; discharged on March 16th. Winifred C—, admitted on Feb. 4th; discharged on March 21st.

Balth P—, admitted to hospital on Dec. 18th, 1905; discharged on Feb. 14th, 1906. Hilda P—, taken ill on Feb. 25th, 1906; treated at home.

Eleanor U—, admitted to hospital on Jan. 20th, 1906; discharged on March 15th. John U—, admitted on March 22nd; discharged on May 22nd.

Cecil A—, taken ill on Feb. 7th, 1906; treated at home. Daisy A—, taken ill on March 31st, 1906; treated at home.

Teddy W—, admitted to hospital on Feb. 6th, 1906; discharged on April 7th. Leonard W—, admitted on Sept. 2nd; discharged on Oct. 15th.

Hilda P—, admitted to hospital on Feb. 8th, 1906; discharged on March 26th. Winifred P—, admitted on March 30th; discharged on May 12th. Ivy P—, admitted on March 30th; discharged on June 16th. George P—, admitted on April 6th; discharged on May 5th.

Annie M—, admitted to hospital on July 21st, 1906; discharged on Sept. 9th. Sarah M—, admitted on Sept. 14th; discharged on Oct. 25th.

George K—, admitted to hospital on Feb. 11th, 1906; discharged on April 18th. Elsie K—, admitted on April 25th; discharged on June 18th.

Eleanor A—, admitted to hospital on March 16th, 1906; discharged on May 10th. Ernest A—, admitted on May 15th; discharged on July 2nd.

Willie D—, admitted to hospital on April 21st, 1906; discharged on June 11th. Arthur D—, admitted on August 3rd; discharged on Sept. 18th. Louie D—, admitted on Oct. 20th.

George C—, admitted to hospital on May 28th, 1906; discharged on July 13th. Florence C—, admitted on Oct. 27th; discharged on Nov. 23rd.

John T—, admitted to hospital on July 29th, 1906; discharged on Sept. 12th. George T—, admitted on Oct. 8th; discharged on Nov. 19th.

Ross B—, admitted to hospital on August 11th, 1906; discharged on Sept. 22nd. Charles B—, admitted on Oct. 9th; discharged on Nov. 23rd. Bertie B—, admitted on Oct. 9th; discharged on Nov. 26th.

Charles C—, admitted to hospital on August 21st, 1906; discharged on Oct. 22nd. George C—, taken ill on Nov. 9th; treated at home.

Hilda H—, admitted to hospital on Oct. 9th, 1906; discharged on Nov. 14th. Edith H—, admitted on Nov. 24th. Martha H—, and Mabel H—, admitted on Dec. 2nd.

Edith O—, taken ill on Nov. 25th, 1905; treated at home. William O—, admitted to hospital on Oct. 29th, 1906; discharged on Dec. 4th.

If the dates of these cases be carefully noted it is surprising to find how long an interval elapsed in some instances after the recovery of the "infecting" case before the development of the disease in the "return" patient. I have been at some pains to eliminate the possibility of fresh infection occurring in these cases. Indeed, in the last case mentioned the time interval seems to be almost incredibly long. But if the infection may persist for some two months why may it not persist longer? The prolonged infectivity of a gleet after a gonorrhoea is recognised as existing for an unknown length of time, and I am inclined to the belief that the scarlet fever infection may similarly persist, lodged possibly in some of the nasal chambers, and that, moreover, it may lie dormant for some time until some suitable condition may render it capable of transmission. I have not a few instances amongst my recorded cases which afford evidence very strongly confirmative of this opinion. I am also inclined to the view that in some of those instances constantly referred to in our text-books, when the poison is presumed to have been harboured in infected garments for a length of time, the spread of the infection may not improbably be due to the harbouring of the infection in the convalescent patient rather than, as has been presumed, in the infected garments.

I ought to add, for our credit's sake, that of the 217 cases isolated in our hospital up to the present time, though there have been many serious cases with grave complications, we have discharged 201 with no deaths, whereas amongst the 114 cases isolated in their own homes there have been three deaths.

Grantham.

A CASE OF DERMOID CYST IN THE RAMUS OF THE JAW.

By N. J. F. VAZIFDAR,

SIR JAMSETJI JEEJEEBHoy HOSPITAL, BOMBAY.

THE patient, a Hindu woman, aged 22 years, was admitted into Sir Jamsetji Jeejeebhoy Hospital on Feb. 1st, 1906, for a tumour in connexion with the right ramus of the mandible. The history of the case was that the tumour—which was evidently of a longer duration—was first noticed about four years back as a hard round mass of the size of a small marble near the temporo-maxillary articulation. There was a previous history of a fall from a staircase when the patient was two years old. The accident was a severe one and the patient had hemorrhages from the mouth, the ears, and the nose. The growth had been quite painless and did not at all interfere with the movements of the joint. It increased very slowly and gradually to its size when seen; it was then three inches in diameter. There were no constitutional effects, the patient keeping excellent health all the time and only seeking advice because of the disfigurement. For the last six months the tumour—perhaps owing to its size—somewhat interfered with the movements of the joint, the jaw could not be opened to its fullest extent, and the tumour was somewhat painful on manipulation. It was smooth, hard, and irregularly round. Its upper limit reached as high as the zygoma and its lower one was at the level of the lower margin of the body of the mandible; anteriorly it came in front of the anterior border of the masseter muscle, whilst posteriorly it approached the posterior border of the ramus. It was firmly fixed to the bone and the skin over it was moveable. There were neither any signs of inflammation nor any implication of the overlying soft parts which were only tightly stretched over the tumour. There were no enlarged glands. Eruption of all the teeth was normal and there had never been any tooth trouble.

All the usual dental tumours being excluded by the normal

eruption and sound condition of all teeth and by the fact of the tumour first appearing at the temporo-maxillary articulation and thence extending downwards, the case was diagnosed as probably one of myeloid sarcoma, and an operation was performed by Lieutenant-Colonel W. H. Quicke, I.M.S., senior surgeon of the hospital. An exploratory incision was first made when the ramus was seen to be expanded from within. The bone being cut open with a chisel and hammer a cyst was revealed filled with soft epithelial-like flakes. The flakes were all removed and the cyst wall, which was partly adherent to and lining the bony cavity, was thoroughly scraped off and removed. The cyst growing inside had also to some extent expanded the body of the mandible where one of the fangs of the third molar was seen. The fang was quite normal. The bony cavity was then cleaned and stuffed with iodoform gauze, and it finally healed by granulation, the healing taking a long time, and the patient was ultimately discharged cured on June 14th.

The case is of interest on account of the unusual site selected by the dermoid. A dermoid within the structures of a bone and at a place where during embryonic life there is no union between two skin-covered surfaces is a surgical anomaly and one which I venture to explain as follows. At birth the mandible is a mere shell of bone containing the sockets of the temporary teeth and covered by the mucous membrane of the gums. Probably by some accident—and perhaps due to the very accident above referred to—a portion of the mucous membrane got into this shell-like bone and remained confined therein, only awaiting some irritation to determine its development into a cyst in the same way as the other so-called implantation dermoids are formed. Another marked feature of the case was the difficulty experienced in diagnosis. The only diagnosis which could be arrived at was that of a myeloid sarcoma, and indeed the appearance of the tumour was quite typical of that disease. The cyst growing inside had expanded the bone in the fashion of a myeloid sarcoma, and in fact there was some obscure sensation of egg-shell crackling at one part of the tumour. The hardness and innocency of the tumour were accounted for by assuming that the sarcoma had undergone a happy termination, viz., ossification, and indeed chondrification and ossification of sarcoma are not uncommon.

I am indebted to Lieutenant-Colonel Quicke for permitting me to report this case.

Bentley.

OF

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est illa pro certo nocendi via, nisi quamplurimas et nobilissimas et disiectissimas historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Prooemium.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

TWO CASES OF INJURY OF THE HEAD IN CHILDREN.

(Under the care of Mr. H. A. T. FAIRBANK.)

CASE 1. Traumatic subdural hæmorrhage without any lesion of the skull.—The patient was a healthy girl, aged one year and nine months. On May 19th, 1906, at 11 A.M. she fell off a chair on to her head. For 15 minutes she seemed all right and ate some bread and butter, then "the eyes became fixed" and she rapidly became unconscious. At 2.30 P.M. she became convulsed on the right side, the head being turned towards the left shoulder. On admission to the Hospital for Sick Children at 3.30 P.M. there was twitching of the right arm and leg and the right side of the face. The head and eyes deviated to the left. The pupils were dilated, equal, and did not react to light. Twitching was soon followed by paralysis of the whole of the right side. There was slight response to pinching but the deep and cutaneous reflexes were absent. With the onset of paralysis the pupils became smaller and remained equal. There was no squint. The pulse was 110 and the temperature was 97° F. At 4.15 P.M. the skull was trephined over the left middle meningeal artery and the hole enlarged backwards. There

was no extradural hæmorrhage. The dura mater bulged tense and blue into the opening and on incising it there was a gush of thin unclotted blood which continued to flow for some minutes and then ceased. The right arm was immediately moved voluntarily and the leg movements soon returned. No bleeding point was found and the wound in the dura mater was closed except for a small gauze drain. Within an hour of the operation the child was quite conscious and there was no trace of paralysis. The dressings were repeatedly soaked with cerebro-spinal fluid in spite of the head being raised. At 11.30 P.M. the temperature had risen to 103°, the respirations were fast and irregular, and the pulse was feeble and rapid. About 6 A.M. on the following morning, as the child was unconscious, the gauze drain was removed and some dark blood escaped. The child died at 7.30 A.M.

Necropsy.—At the post-mortem examination no fracture of the skull, gross lesion of the brain, or rupture of blood-vessels was found. There was a marked scarcity of cerebro-spinal fluid and between the dura mater and the brain on the side of the operation was a thin film of blood—quite insufficient to produce symptoms.

CASE 2. Fracture of the skull with cerebral symptoms.—A boy, aged four years and three months, was admitted to the Hospital for Sick Children on August 1st, 1906. 20 minutes before admission he fell off the steps of a tramcar on to the street, a height of about six feet, landing on his head. He seemed dazed by the fall, but did not lose consciousness and was able to walk. Ten minutes later the left arm and left side of the face were noticed to twitch and later the right side also twitched. He vomited and became drowsy and was at once taken to the hospital. On admission he was quite unconscious and was having clonic convulsions of all the limbs and face as much on one side as on the other. Ten minutes later the convulsions had entirely passed off and the limbs were quite flaccid. The breathing was stertorous. The pupils varied constantly in size, being at one moment dilated, at the next contracted, but always remaining equal. The pupils reacted sluggishly to light. The head and eyes deviated first to one side and then to the other. There were no facial paralysis and no squint. The knee-jerks were present and a flexor response was obtained in the right foot but none in the left. There was a hæmatoma above the right ear. No depressed fracture was made out.

Operation was performed about 50 minutes after the accident. No anæsthetic was given during the initial stages of operation. A little chloroform was administered later. A flap of scalp was turned down above and in front of the right ear. A fissured fracture was found running horizontally backwards from the external angular process of the frontal bone and extending beyond the limits of the wound which measured two and a half inches across. There was no depression of fragments. The skull was trephined just below the anterior part of the fissure. There was no extradural hæmorrhage and the dura mater pulsated feebly. On enlarging the trephine hole backwards a local bulging of the dura mater, somewhat dusky in colour, was exposed. A small incision was made through the dura mater at this spot but no blood was found within reach of the puncture. The dura mater was closed by a couple of stitches and the flap sutured in place. After the operation the boy was restless and even violent, but after about seven hours he regained consciousness. From that time he made an uninterrupted recovery.

Remarks by Mr. FAIRBANK.—Grave cerebral symptoms which are the result of traumatism and which call for surgical interference are so rarely met with in children that the above cases seem worthy of publication. In the first case the indications for treatment were sufficiently clear, though want of experience of such injuries in young children rendered the diagnosis of the source of the blood doubtful. The disappointing termination after the symptoms had been entirely relieved by operation was probably the result of the loss of cerebro-spinal fluid. Yet it did not seem to be a wise procedure to close the dura mater entirely without drainage, since the source of the hæmorrhage had not been discovered. The procedure was justified by the occurrence of the second small hæmorrhage. The result of the post-mortem examination showed that it would have been useless to hunt for the ruptured vessel.

In the second case the localisation of the lesion would have been difficult but for the presence of the hæmatoma over the right motor area, the region of the brain which the symptoms seemed to indicate as involved in the injury. The operation only revealed the presence of a

fractured fracture, so the cause of the cerebral symptoms must be left in doubt. The presence of minute hæmorrhages into the cerebral cortex may be suggested as an explanation. Since the incision made in the dura mater was minute and the hole in the skull not very extensive, it is difficult to see how intracranial tension can have been relieved to any extent by the operation. Unless the trephining did some good in this way it necessarily follows that probably the child would have recovered with equal rapidity had nothing surgical been done.

LIVERPOOL WORKHOUSE HOSPITAL.

RUPTURE OF THE SPLEEN; SPLENECTOMY; RECOVERY.

(Under the care of Dr. W. ALEXANDER.)

FOR the notes of the case we are indebted to Mr. John T. Moore, resident medical officer.

The patient, aged 34 years, a labourer and an ex-soldier, was admitted into the Liverpool workhouse hospital on August 5th, 1906, complaining of pain in the left side of the abdomen. He stated that upon the night before admission, while under the influence of drink, in the course of a row with another man, he fell over a form and hurt his side. After the injury he went to bed and slept. The next morning he arose at the usual time and went to his work, which consisted in wheeling a heavy barrow. He commenced work at 5 A.M. and struggled on till noon. During this time he felt bad and had two pints of beer, part of which he vomited. He then sought admission to the hospital.

On admission the patient complained of severe pain in the left hypochondrium. His temperature was normal. There were no signs of injury or fracture of the ribs. Opium stupes were ordered and later he said that he felt better and slept fairly well. On the evening of the next day, August 6th, the pain in his side became intense; he vomited three times, his respirations became frequent and chiefly thoracic, the pulse was small and frequent, and the temperature fell to 97.6° F. The abdomen was retracted and the liver dulness was apparently diminished. It was evident that some serious internal injury existed. An exploratory operation was proposed and agreed to by the patient. The abdomen was opened at 8.30 the same evening by a median incision. The left hypochondrium was found full of blood clot and the spleen ruptured. The vertical incision was now prolonged to the left just below the costal margin. The blood was confined to the left hypochondrium and the colon was distended, which accounted for the diminished liver dulness. Bright blood was gushing up from the left. The spleen was at once brought into view, having to be scraped off the parietes owing to old adhesions. It was found to be surrounded by firm clots and to be ruptured in two places. The pedicle was clamped, the spleen was excised, the stump ligated, and the blood clot was removed. The patient at this stage became extremely collapsed. An intravenous injection of 30 ounces of normal saline solution containing one drachm of 1 in 1000 adrenalin solution was given by Dr. R. Donaldson whilst the operation was rapidly completed. After the removal of blood and clots the cavity was swabbed out with saline solution containing adrenalin, and as there was some oozing and the patient was much collapsed the large cavity was packed with sterile gauze and two large gauze drains in split rubber tubes were placed in the lower corner of the wound. The incision in the abdominal wall was closed in the usual three-tier way. He was removed to bed, the lower end of which was well raised. He had small rectal salines and fluids by the mouth every two hours, strychnine hypodermically (1/20th of a grain) every four hours, and 1/4th of a grain of morphine to check the intense restlessness. The temperature remained at 97° and the pulse was very small, 130 during the night. The shock continued to a considerable extent all the next day, the pulse being from 130 to 136. At 4 P.M. the temperature rose to 100.4°, gradually coming down to normal towards morning. The patient was fed with small quantities frequently, meat juice, beef-tea, chicken broth, and egg fillet alternately, and four-hourly rectal nutrients were administered. On the 8th the shock had passed off, the gauze and drainage tubes were removed, and small gauze drains were applied. During the day he vomited three times and the bowels were moved; at night he had a troublesome cough which was relieved by jacket poultices and a steam tent. On the 9th his condition was about the same. On the 10th the wound was again

dressed. Vomiting had ceased, but the cough was troublesome. Bronchitis was present all over the chest and there was friction at the right base posteriorly. The temperature went up to 101°. From this date the patient's condition improved daily: his chest cleared up, the temperature became normal, the wound was dressed every second day, and the convalescence was uneventful except for another attack of pleurisy and bronchitis which lasted for about a week. A blood count early in October showed 3,967,480 red cells and 6758 white cells per cubic millimetre. The patient went to town quite well on Nov. 20th.

The spleen was a shade larger than usual at the time of removal; it was somewhat collapsed and there were two holes in its surface through which blood was seen oozing before the pedicle was clamped.

Remarks by Dr. ALEXANDER.—There are several points in this case that are of interest to the profession. The history of the case, though not reliable owing to the partial intoxication of the patient, points to a fall over a form and the injury to the spleen would probably not have occurred but for the adherent condition of that organ. Its convex surface was fixed to the diaphragmatic peritoneum and had to be peeled off by the fingers at the operation. It could not move to avoid the crush and so was injured when a moveable spleen would probably have escaped. Again, the hæmorrhage was at first undoubtedly inside the capsule and had the patient been able to rest it might never have gone beyond that position. But after a good night's rest he had to get up and work "wheeling a barrow." Even when he came into hospital the same afternoon he was not in an alarming condition, nor did he show urgent symptoms until the next morning. The rupture of the splenic capsule probably did not take place until some time after he was in bed in the hospital, as at the operation the blood was entirely confined to the left hypochondrium. This would hardly have occurred had bleeding been going on whilst the patient was moving about, as blood would in that case have trickled down into the lower abdomen. It was especially noticed that this had not occurred.

The next point is that we did not operate on account of a ruptured spleen. We did not know what had taken place but the symptoms indicated grave internal lesions and the operation was at first exploratory only. The retraction of the abdomen and the lessened liver dulness pointed rather to an injury of a hollow viscus than of a solid organ. The collapse, the rapidly falling pulse, the shallow breathing, &c., all called urgently for an exploration, and as an exploration in itself is not dangerous, nor does it add materially to the gravity of the case, we performed it, although we had no idea at the time of the nature of the injury.

An important point in the case is the great and manifest value of adrenalin and saline transfusions. After the spleen was removed the condition of the patient became alarming, and the feeling of my anaesthetist and of some of my assistants was that the patient was dying. Dr. Donaldson rapidly inserted the transfusion needle into the usual vein in the arm and passed one drachm of adrenalin solution mixed with one and a half pints of normal saline solution into the circulation. The effect was immediate and enabled me to finish the operation satisfactorily. The value of adrenalin was also shown in its effect on the oozing from the bleeding surfaces from which the ruptured spleen had been removed. The oozing ceased as if by magic when we pressed on the bleeding surface gauze soaked with adrenalin solution, and we were then able to place our gauze drains in position comfortably.

On August 10th I left for Canada and Mr. Moore took entire charge of the case. The credit of piloting the patient through various pulmonary complications is entirely due to his care and skill. When I came back the patient was convalescent, his blood count was practically normal, and there were no signs that such an important organ had been removed.

PRIVATE ASYLUMS FOR THE INSANE IN ST. PETERSBURG.—At a recent sitting of the St. Petersburg town government it was decided to make an experiment by subsidising private homes to the initial extent of £1000 for patients of weak mind, so as to relieve the pressure on the hospitals. Although some members argued that the step was calculated to encourage "angel making" the decision was given in favour of the argument of others who held that there were many wholly trustworthy people to whom the care of insane persons might be given.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Demonstration on the Spirochæta Pallida.—A Note on the Pathology of Syphilis.—Observations upon Cheyne-Stokes Respiration.

A MEETING of this society was held on Jan. 8th, Mr. W. HARRISON GRIFFS, a Vice-President, being in the chair.

Dr. ALEXANDER MACLENNAN gave a demonstration on the *Spirochæta Pallida*. He said that it could not be definitely settled that the organism was the infective agent in syphilis. This could only be done by successful cultivation and inoculation. He could, however, accentuate the following points: 1. The organism had not been found in experimentally infective material. 2. It was admittedly scarce in the surface discharge in primary and secondary lesions, possibly because the organism was anaerobic. 3. Congenital syphilis was considered to have a low infective power while its lesions teemed with spirochæta. On the other hand, the infectivity of the tertiary lesions was more in conformity with the numbers of spirochæta present. 4. Smaller forms which were related to the spirochæta were invariably present in preparations from the lesions. He did not consider that there were sufficient data to accept definitely the spirochæta pallida as specific, but he accepted its presence as diagnostic of syphilis. This might seem rather paradoxical, but the explanation was that the spirochæta pallida was only one phase in the life cycle of the infecting organism. He then demonstrated by means of lantern slides the various stages and the method of reproduction. Two methods were described, one by longitudinal division and the second by the formation of "buds." These two methods might occur in the same spirochæta. He then demonstrated the life cycle of the organism.

Mr. J. JACKSON CLARKE read a preliminary note on the Pathology of Syphilis. He said that the object of his communication was to call attention to the connexion between the spirochæta pallida described by Schaudinn in 1905 and the protozoa in syphilitic lesions which he described ten years ago. Those acquainted with the commoner parasitic protozoa would recognise the striking resemblance of these bodies to such protozoa. Diagrams were shown illustrating this resemblance. Mr. Clarke believed that the bodies which he had described in 1895 were homologous with the "gregarine" phases of the spirochæta Ziemanni as described by Schaudinn. The gregarine-like bodies occurred in such great numbers and were distributed in the lesions of syphilis in such a way that the causal relationship of the mobile spiral forms (spirochæta or spiroplasma) to the disease must remain doubtful unless they could be shown to be members of the same cycle that also included these gregarine-like forms.

Dr. FREDERICK TAYLOR said that he, in conjunction with Dr. M. S. Pembrey, Dr. A. P. Beddard, and Dr. Herbert S. French, had made certain observations on two cases of Cheyne-Stokes Respiration. The first case was one of typical Cheyne-Stokes respiration lasting almost continuously for over six months in a patient who was proved by necropsy to be suffering from chronic renal disease, and in whom Dr. E. Farguehar Barnard had examined the pons and medulla microscopically and had found many foci of softening around sclerosed arteries. The second case had equally typical Cheyne-Stokes respiration following upon injuries received in a lift accident; he recovered so that the precise lesion was not verified. In each case, amongst other investigations, the effects of giving the patients (1) pure oxygen; and (2) air containing high percentages of pure carbon dioxide, were recorded graphically. The supply of oxygen and of carbon dioxide respectively was controlled by a tight-fitting mask with appropriate valves. The periodicity of Cheyne-Stokes respiration in both cases was converted into the continuous respiration in both cases by the administration either of excess of oxygen or of excess of carbon dioxide. The conclusions which were submitted for discussion were—That apparently the periodicity of Cheyne-Stokes respiration was in great part due to a diminished excitability of the nervous system associated with a defective supply of arterial blood; the carbon dioxide

accumulated and the oxygen diminished until at last the nerve cells were stimulated, the waxing respirations began and culminated in hyperpnoea whereby a large quantity of carbon dioxide was washed out and sufficient oxygen was taken in; apnoea followed, due apparently to the absence of sufficient carbon dioxide to stimulate the nerve cells. That the inhalation of air containing more than 2 per cent. of carbon dioxide abolished apnoea by maintaining the partial pressure of the carbon dioxide in the alveolar air and blood at its stimulating value. That the administration of pure oxygen by means of a mask and valves abolished apnoea by maintaining the partial pressure of carbon dioxide in the blood at its stimulating value; the respiratory centre was no longer excited by lack of oxygen to send out the forcible impulses which had previously resulted in excessive ventilation of the lungs whereby carbon dioxide had been washed out of the alveoli and lungs.

Dr. M. S. PEMBREY said that he, in conjunction with Dr. G. Newton Pitt and Dr. R. W. Allen, had made observations upon Cheyne-Stokes Respiration. The patient was admitted under the care of Dr. Newton Pitt with aortic incompetence and a history of some temporary weakness of the right arm of doubtful origin some months previously. He shortly developed a slight left hemiplegia with marked Cheyne-Stokes respiration, which persisted for three months till the time of his death, on which Dr. Pembrey and Dr. Allen made many observations indicated below. There was also incontinence of urine which varied but never cleared up entirely. At the inspection there were found a large area of softening involving the region round the Sylvian fissure on the right side, and degenerative changes in the vagal nucleus. Dr. Hoffmann insisted that persistent incontinence, of cerebral origin, was always due to bilateral cerebral lesions, but in this case the lesion was one-sided, though the incontinence was not so persistent as in the cases he referred to. It was found that the Cheyne-Stokes respiration could be controlled and abolished either by giving the patient pure oxygen to breathe, by increasing the amount of the carbon dioxide, or by diminishing the amount of the oxygen in the air respired, or by certain combinations of these proceedings. They concluded that the periodicity of Cheyne-Stokes respiration was due to a diminished excitability of the nervous system; the carbon dioxide accumulated and the oxygen diminished until at last the nerve cells were stimulated, the waxing respirations began and culminated in marked dyspnoea, whereby the carbon dioxide was washed out and a large quantity of oxygen was taken in; apnoea then followed, due apparently to the absence of sufficient carbon dioxide to stimulate the nerve cells. This view of the condition of the nerve cells of the respiratory centre was amply confirmed by the microscopic examination obtained after death—only a small proportion of the cells of the vagal nucleus having a normal appearance.

OBSTETRICAL SOCIETY OF LONDON.

Chronic Metritis.

A MEETING of this society was held on Jan. 2nd. Dr. W. R. DAKIN, the President, being in the chair.

Dr. ARCHIBALD DONALD read a paper on Chronic Septic Infection of the Uterus and its Appendages. Dr. Donald dealt chiefly with septic infection which involved the uterine appendages as well as the uterus. The cases in which the uterus was chiefly involved were discussed more fully. The clinical history and symptoms of these cases were considered and special attention was drawn to the discomfort or pain which was felt in the hypogastrium or iliac regions and which was so characteristic of a heavy uterus. In dealing with the pathology of chronic metritis the great divergencies of opinion as to the microscopic anatomy were noted. The three main theories as to the cause of chronic metritis were discussed—namely, (1) passive congestion; (2) inflammatory change; and (3) muscular hypertrophy. Reasons were given why the mere alteration in position of a healthy uterus was not likely to cause passive congestion and chronic metritis, but it was pointed out that the treatment by pessaries and suspension operations was founded on the assumption that a displacement did cause these changes. Dr. Donald objected to the use of pessaries and the performance of suspension operations for cases of mobile retroversion on the ground that these methods could never

cure the chronic metritis, which was at the root of most of the symptoms.

Dr. W. FLETCHER SHAW then gave a lantern demonstration and read a paper on the Pathology of Chronic Metritis. The conclusions arrived at in this paper were the results of the examination of 45 uteri extirpated for chronic metritis, 38 being uncomplicated cases, while seven occurred with some concurrent pathological condition. For the purpose of comparison 23 normal uteri were also examined. The main results arrived at were as follows. Chronic metritis was a simple hypertrophy of the mesometrium and was not a connective-tissue hyperplasia. The vessel changes were variable, and as similar affections were as frequently found in normal uteri they could not be considered as the cause of the symptoms. Except two cases, which could be easily explained, every specimen of uncomplicated chronic metritis also suffered from chronic endometritis. There was no evidence of active inflammation, as shown by small-celled infiltration or cicatricial tissue. Chronic metritis was a slowly progressing affection of the uterus. It was never a primary affection, being usually secondary to chronic endometritis, but might be associated with any pelvic or uterine disease leading to increased uterine contraction or vascularity—viz., fibroids, tubo-ovarian disease, &c. Chronic metritis occurred at a much earlier age than the menopause and thus proved that the climacteric was not the causal factor. The diagnosis of chronic metritis was largely dependent on the result of treatment. In the early stage of the affection all the symptoms disappeared after dilatation and curettage of the uterus, thus demonstrating that the endometritis was the primary cause. In chronic metritis and chronic endometritis local treatment of the endometrium might fail to relieve the symptoms. This was probably due to re-inauguration of the endometritis.

The PRESIDENT thanked Dr. Shaw for his valuable paper. It was an important step towards putting the study of so-called "metritis" on a scientific basis. The President used the term "so-called metritis" because so far as he could see there was nothing indicating inflammation in any of Dr. Shaw's sections or descriptions; in fact, both "metritis" and "endometritis" as used at present by many did not necessarily mean anything connected with inflammation. These terms, however, led students and others astray and ought to be reserved for inflammatory processes. He would appeal to both Dr. Donald and Dr. Shaw, as among the pioneers in this research, not to countenance such misuse of terms.

Dr. CULLINGWORTH, speaking of the papers by Dr. Donald and Dr. Shaw, said that the two authors, though both were Manchester men, had not worked in collaboration, but approached the subject independently, the one from a clinical, the other from a pathological standpoint; they had gradually become aware of each other's work and of the fact that the conclusions at which they had arrived were practically the same.

Dr. AMAND J. M. ROUTH said that no subject in minor gynaecology was more perplexing than that of chronic metritis. Did Dr. Donald and Dr. Shaw consider all their cases to be "septic" in origin? Were not some of them really of the type usually known as arterio-fibrosis of the uterus?

Dr. H. RUSSELL ANDREWS said he thought that Dr. Shaw deserved the thanks of the meeting for his clear demonstration of the fact that there were no characteristic histological changes in "chronic metritis." One reason why some gynaecologists were loth to accept chronic metritis as a clinical entity was that the slides and micro-photographs used to illustrate some papers on this subject showed changes in the muscle, connective tissue, and vessel walls which were said to be pathognomonic of chronic metritis though they differed in no way from what was seen in normal multiparous uteri. He thought that this was one of the most interesting points in a very interesting demonstration.

Dr. OUTHBERT LOCKYER expressed his hearty appreciation of Dr. Shaw's admirable and painstaking work upon the much vexed question of the pathology of so-called chronic metritis. He thought that the society owed a debt of gratitude to Dr. Shaw for his paper and demonstration which constituted the first really scientific attempt at evolving order out of chaos (as far as this subject was concerned) which had been presented for discussion at the Obstetrical Society of London. Dr. Lockyer particularly noted that Dr. Shaw's series of cases did not include one type of uterus in which he himself was

especially interested and to which attention had been drawn by Dr. J. R. Goodall at the meeting of the British Medical Association at Toronto in August, 1906—viz., the arterio-sclerotic uterus. Attention had been drawn to this condition not only by Dr. Goodall but by Dr. A. H. Freeland Barbour in a paper entitled "Climacteric Hemorrhage due to Sclerosis of the Uterine Vessels," and, as that writer states, the only remedy for the hemorrhage was removal of the uterus. Dr. Lockyer cited a similar case from his own practice at St. Mary's Hospital, Plaistow, and it was surprising to him that in such an extensive research Dr. Shaw had not met with this condition. Dr. Lockyer would therefore like to hear from Dr. Shaw whether he regarded every case of so-called chronic metritis as of infective origin, or if he would admit the entity of a primarily arterio-sclerotic uterus occurring independently of any source of infection from without.

Dr. FRANK E. TAYLOR said that he had been much impressed by two points during the routine pathological examination of a considerable number of uteri, similar in character to those described by Dr. Donald and Dr. Shaw, which had been removed on account of excessive and intractable hemorrhage. The first point was the extreme variability of the histological findings presented by the various specimens examined, some uteri presenting histological features which differed very slightly from those of normal uteri, whilst others presented most striking changes, especially as regards the thickness of the vessel walls in the myometrium. All intermediate stages were likewise observed. The second point was the lack of a normal standard with which to compare the conditions found in chronic metritis—as to what amount of thickening of the vessel walls in the myometrium could be considered pathological and as to the significance of the relative proportion of fibrous to muscular tissue present, along with the difficulty of definitely ascertaining this proportion. Both Dr. Donald and Dr. Shaw had laid great stress on the importance of infection as a causative factor in the etiology of chronic metritis and had mentioned the frequency with which the symptoms dated from a confinement or miscarriage presumably septic. Now gonococcal was probably as frequent as puerperal infection of the pelvic viscera. Hence it might have been expected, if infection were really an important factor, that a history of gonococcal infection would have been present in a certain proportion of the cases, but of such a possible origin neither Dr. Donald nor Dr. Shaw made any mention.

Dr. DONALD and Dr. SHAW replied.

LIVERPOOL MEDICAL INSTITUTION.

Duodenal Ulcer.—Operations during Typhoid Fever.—Lymphatic Leukæmia.—Forgotten Medical Worthies.

A MEETING of this society was held on Dec. 20th, 1906, Mr. FRANK T. PAUL, the President, being in the chair.

Mr. G. P. NEWBOLT read notes of a case of Perforating Duodenal Ulcer complicated by Abscess of the Lung in a male patient, aged 30 years, who had previously been in robust health. The treatment was by injections of polyvalent serum. Frequent attempts were made to localise the abscess with exploring needles; the abscess eventually emptied itself, on some days from a pint to a pint and a half of pus being expectorated. Finally the patient made a good recovery. The organism isolated conformed to the type of streptococcus termed *streptococcus salivarius* by Andrewes and Horder.

Mr. W. THRELWALL THOMAS read notes of two cases of Surgical Operations during the Course of Typhoid Fever—one for perforation and one for appendicitis—both of which terminated in recovery. He drew attention to the fatal character of perforation unless surgically treated, when the recovery rate was 30 per cent. or more. Although in many cases the diagnosis was uncertain it would be wiser to explore (under local anaesthesia) than to wait until general septic peritonitis had set in. The treatment of the perforation by quick suture or the formation of a fecal fistula appeared to be the two alternatives—fancy work such as enterectomy with end-to-end anastomosis was not to be recommended; enterostomy had the further advantage of draining the typhoid intestine and keeping it at rest. The first patient was a man who had been walking

about until a few days before symptoms of perforation occurred; the case was diagnosed as perforative appendicitis and was immediately operated upon with the result that a typhoid perforation was found. The second patient was a young woman in the third week of typhoid fever; though a provisional diagnosis of perforation was made at the operation acute appendicitis was found. Mr. Thomas briefly described two other previous cases in which he had operated for typhoid perforation without being able to save the patients' lives.—The PRESIDENT referred to two cases: one illustrating the difficulty of making a certain diagnosis in typhoid perforation; in the other a perforation 12 inches from the cæcum occurred three months after the onset of typhoid fever. In the latter case the ulceration was so extensive that the perforation could only be closed by excising it and the patient died nine days after the operation.—Mr. T. O. LITTLE JONES mentioned a case which he had operated upon successfully last July. A lascar boy was taken to the Liverpool Infirmary at the end of the second day after perforation of a typhoid ulcer. Simple suture of the ulcer was performed and the abdomen was cleaned of intestinal contents. The boy was transferred to his ship three weeks afterwards. Perforation was rare in Hindus and the infection was comparatively slight.—Mr. R. W. MURRAY said that better results from operative interference would probably be obtained if, as a general rule, the bowel at the point of perforation was brought to the surface and a fecal fistula temporarily established. Such an operation could be quickly performed and would have the great advantage of permitting the inflamed bowel to rest.

Dr. R. J. M. BUCHANAN read a paper on Acute Lymphatic Leukæmia. He drew attention to the rarity of the disease and said that in its symptom complex it resembled in many ways an acute specific fever. The blood picture was one quite different from that seen in myeloid leukæmia and was due to a hyperplasia of definite cell elements. The features of the disease were illustrated by an acute case of nine days' duration in which the symptoms pointed in the later stages, on the one hand, to a morbid state of the blood and, on the other, to an acute abdominal lesion, most probably hæmorrhage into the pancreas. A blood count revealed a lymphocytosis of 523,000 per cubic millimetre. The case was under the care of Dr. O. R. Scholfield of Southport, to whom Dr. Buchanan expressed his thanks for the notes of the early condition.—The paper was discussed by Dr. E. E. GLYNN, Dr. W. CARTER, and Dr. R. R. HURTER.

Dr. A. CASSELS BROWN read a paper entitled "Two Forgotten Medical Worthies." The subjects of the paper were Dr. Gabriel Broughton and Dr. William Hamilton, both of whom played somewhat important parts in the early struggles of the "Company" in India.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Patients.

A MEETING of this society was held in the Edinburgh Royal Infirmary on Dec. 19th, 1906, Professor W. S. GREENFIELD, Vice-President, being in the chair.

Mr. J. M. COTTERILL exhibited the two following cases. 1. The Rare Condition of Lympho-Sarcoma occurring in the Lower Part of the Neck in a Young Man. He said that the diagnosis of such cases was difficult and that they were frequently mistaken for fibro-lipomata or tuberculous disease. The disease grew very quickly and irregularly; it also became adherent to the skin and other tissues without pain or inflammation and in both these respects it differed from tuberculosis. Tuberculosis of the glands usually began high up in the neck; this disease, however, usually commenced in the mediastinum or axilla and extended upwards to the neck. In the case described it occupied the lower portion of the neck on the left side and extended under the trapezius muscle. 2. A case in which Decompression for Brain Tumour gave great relief from the urgent symptoms. The patient was a man and the diagnosis was very difficult. A large piece of the frontal and parietal bones was removed for purposes of diagnosis. As it was impossible to remove the cerebral tumour, the bone was not replaced, thus allowing of a large hernia of the brain. This relief of pressure had afforded the patient great comfort, the intense headache from which he formerly suffered having disappeared and the sight in the left eye having undergone improvement; photophobia, which formerly was present, had disappeared. Mr. Cotterill referred

to another case in which he had removed a portion of bone with the result that a large hernia of the brain of the size of the two fists had formed. This gradually became absorbed and at the present time, eight years after the operation, the patient had only a depression in the skull and had almost completely recovered from his former condition.

Dr. ALEXANDER BRUCE showed a man suffering from Primary Progressive Myopathy. The condition was in the family and a brother of the patient suffered much in the same way. The muscles of the back and the gluteal muscles were so weak that the man had to throw his shoulders far back, so placing his centre of gravity well behind his feet. The most peculiar feature of the case lay in the marked atrophy of the muscles of the proximal parts of the arms and lower extremities. The hands remained almost as strong as ever and so did the muscles of the forearm, but the upper arm was very weak; the biceps was atrophied and he possessed very slight power of flexing his elbow-joint. In the right arm certain fibres of the triceps were well developed. There was a marked atrophy of the clavicular fibres of the pectoral muscles and there was a certain degree of alar winging. The thigh resembled the upper arm in the atrophy of its muscles, but the calves were very well developed, as were the muscles of the forearm.

Dr. R. CRANSTON LOW showed a case of Keloid Acne which had undergone great improvement after 12 exposures to the x rays during six months.

Mr. H. ALEXIS THOMSON showed a man, aged 45 years, after Incision and Drainage of a Mesenteric Cyst. It contained semi-fluid material of the colour of *café au lait* with fat droplets and cholesteroline. The cyst wall was partly calcified. The operation was performed three years ago and a sinus was still present.

Mr. C. W. CATHCART showed a patient after removal of the Gasserian Ganglion for Epileptiform Neuralgia. The patient, who was a woman, 35 years of age, was admitted to the Edinburgh Royal Infirmary on Nov. 4th, 1906, on account of severe epileptiform neuralgia on the right side of the face, head, and neck. The symptoms began about three and a half years ago by a pain in the lower jaw, coming on in spasms. After these had continued for about a year and had gradually increased, she was admitted on account of the pain to a hospital, where an operation was performed on the side of the neck. Portions of the cervical nerves supplying the face and neck were excised as the pain seemed to be most felt in the distribution of those nerves. The patient declared that she was worse after this operation and that the pain extended into the region of the upper as well as into the lower jaw. The teeth in both sides of the upper jaw were removed with no improvement. The teeth in the lower jaw were then also removed but without benefit. Portions of the supra- and infra-orbital, and mental nerves were then excised and for a month the patient was free from pain. It afterwards, however, returned and was only partially relieved by morphine, strychnine, bromide, and quinine. In October, 1906, she was under Dr. Byrom Bramwell's care for a fortnight and the hypodermic injection of strychnine in gradually increasing doses was tried but without avail. On going home after leaving the infirmary she was attacked by the pain with renewed vigour and was taken into the surgical side as no further medical treatment seemed available. She was fairly well for about a week but after that time the pains returned with terrible severity and her condition became pitiable. The whole ward was disturbed by her cries night and day in spite of large doses of morphine. The operation for removal of the ganglion was undertaken on Dec. 5th by Cushing's median direct method. A horseshoe incision was carried from the external angular process of the frontal bone to a point just in front of the ear. The skin flap was thrown down, the zygoma cleared of periosteum and removed, as well as a portion of bone in the temporal fossa extending from a little below the level of the anterior inferior angle of the parietal bone to a little below the infra-temporal crest. The brain and dura mater were lifted up and the ganglion was seized with forceps after having been freed from its sheath of dura mater. The superior maxillary division of the fifth nerve was torn through while the ganglion was being separated from the dura mater. The ophthalmic division of the fifth nerve was divided with scissors just as it left the ganglion and the inferior maxillary division of the fifth nerve was divided. In being twisted out the ganglion gave way where it was joined by the sensory root, but the latter had meanwhile been torn out of the pons and was easily removed after the ganglion had been taken away. The patient had made a

good recovery. She had had no pain in the head or neck, although the operation was performed in the middle of one of her bad periods. The regions of the distribution of the three divisions of the fifth nerve were now quite anæsthetic. It was noteworthy that in spite of the removal of portions of the three divisions of the fifth nerve, as well as of several branches of the cervical plexus to the head and neck, sensation had returned in all the regions which had been at first rendered anæsthetic by these operations.

Dr. EDWIN BRAMWELL showed an unmarried woman, aged 36 years, with very pronounced Weakness and Wasting of the Muscles of the Left Arm and Hand supplied by the seventh and eighth cervical and first dorsal spinal roots. There was some objective sensory loss in the corresponding distribution, while the left eye presented the oculo-pupillary syndrome which resulted from a destructive lesion of the cervical sympathetic. These symptoms had developed gradually three years previously and their onset had been accompanied by severe pains in the region of the left shoulder and the ulnar aspect of the forearm. At a later date paralysis of the right external rectus and of the right side of the face, together with deafness in the right ear, had developed. In addition there had been some paresis of the left lower extremity. The coexistence of two independent and probably extra-medullary lesions was suggestive of syphilis. A cutaneous scar presented characteristics of a healed luetic ulcer. The diagnosis was confirmed by the rapidity with which the cranial nerve palsied; the paresis of the left leg and the paresis in the left arm had yielded to anti-syphilitic treatment.

Dr. GEORGE MACKAY showed a miner incapacitated for work by Vertical Diplopia and wearing strong prisms nine months after a penetrating injury of the orbit by a piece of steel. The fragment was localised by the x rays and its removal was aided by Volkmann's magnet. The diplopia was practically removed by tenotomy of the superior rectus.

Dr. R. W. PHILIP showed a case of Extreme Dyspnoea successfully treated by means of Béraneck's tuberculin. The patient, who was a woman, aged 40 years, was sent to Dr. Philip's ward in the Royal Infirmary by Dr. John R. Hamilton of Hawick. She had been for four months in a sanatorium and had improved somewhat, having put on about 2 stones in weight. None the less she had remained extremely breathless, the dyspnoea being more or less constant and from time to time paroxysmally aggravated. The dyspnoeic attacks were most formidable and sometimes threatened suffocation, especially by night. Examination of the chest showed, in addition to considerable areas of dulness, a large number of rhonchi. The symptoms and signs had suggested the probability of pressure by enlarged, presumably tuberculous, bronchial glands. On this hypothesis Dr. Philip had treated her with tuberculin, using Béraneck's preparation. Commencing with 0.1 cubic centimetre of 1 in 100,000 saline solution he had gradually passed to 0.3 cubic centimetre of 1 in 10,000, the tuberculin being administered at intervals of two or three days. After the first few doses the dyspnoea began to lessen and for the last 12 days the patient had been completely free not only from the paroxysms but from breathlessness altogether. Her nights were completely undisturbed. Examination of the chest showed it to be free from respiratory accompaniments.

Mr. JOHN W. DOWDEN demonstrated cases of Fracture about the Elbow-joint.

Dr. HARRY RAINY showed a case of Paralysis Agitans which exhibited several unusual symptoms.

Mr. JOHN W. STRUTHERS showed a patient after recovery from Chronic Intussusception with Inversion of the Vermiform Appendix.

Mr. A. A. SCOT SKIRVING showed two patients after operation for Ruptured Gastric Ulcer.

Mr. E. W. S. OARMICHAEL showed a child, aged two and a half years, whose Cæcum and Ascending Colon had been Resected 16 months previously for tuberculous stricture.

Mr. L. O. PERL RITCHIE showed several cases of Surgical Tuberculosis treated by Tuberculin R.

Dr. G. A. GIBSON showed a case of Landry's Paralysis.

• ROYAL ACADEMY OF MEDICINE IN IRELAND.—A meeting of the Section of Obstetrics was held on Dec. 14th, 1906, Dr. R. D. Purefoy, the President of the Section, being in the chair.—Mr. G. R. Seymour Stritch described a New Form of Pessary which, he said, supported the uterus, in a patient,

aged 80 years, without pressing on an ulcerated cervix. The pessary was made in the form of a ring, supported by a vaginal stem, from the vulvar ends of which tapes were attached for fixation to a waistband. The ring could be hinged against its stem to facilitate its insertion and when in position it could be locked at the required angle to the stem. The uterus hung within the ring free of pressure irritation. The manufacturers were Messrs. Down Brothers of London.—Sir W. Smyly said that in two important points—namely, the joint and the waist attachments—Mr. Stritch's pessary was a distinct improvement on former ones.—Dr. Henry Jellett showed a Uterus affected with Cancer of both Cervix and Fundus. He said that cancer of the cervix was in the past considered to be one of the indications for supra-vaginal amputation of the cervix and he thought this specimen showed the untenable nature of such a position. The specimen was also a rare one, and Oullen in his work on cancer of the cervix only recorded half a dozen cases. Cases of cancer occurring at both the fundus and the cervix might be divided into two classes—namely, (1) those in which the two cancers were independent of one another; and (2) those in which it was possible to trace definite connexion. In the present case of a patient, about 54 years of age, he had operated for cervical cancer and had no reason to suspect fundal cancer. The first thing he saw on opening the abdomen was a slight adhesion of the intestines to the fundus. The operation was a fairly radical one and the patient unfortunately died from the shock 14 hours after. The operation had to be very extensive, on account of the necessity of taking away almost the entire upper third of the vagina. In the specimen a fine line of connexion could be seen between the two growths, and this presumably followed the lymphatics traversing the muscular wall from one growth to the other. The operation was performed by Werder's method, as described in Oullen's "Cancer of the Uterus."—The President said that the case reminded him of one that had been under his care, in which the uterus contained two varieties of cancer, one in the cervix and one deep in the tissue of the fundus, no microscopic or macroscopic connexion being between them. The disease in both localities was not very far advanced and the patient made a good recovery.—Sir W. Smyly presented a specimen of Ovarian Cyst. He said that the case showed all the characteristics of an ovarian tumour except that he could not isolate the uterus from the tumour. The uterus moved with the tumour and though he thought that it was ovarian in origin he could not make a positive diagnosis.—Dr. Alfred Smith showed a Vesical Calculus with a Nucleus consisting of Pedicle Silk. He said that about three months after the removal of a large ovarian cyst the patient began to suffer increasing pain during micturition and her medical adviser was satisfied that she had stone in the bladder. Her abdomen was so tender that it could not be palpated without an anæsthetic, but when the anæsthetic was administered he found the bladder filled with stone. Having crushed the stone and washed out the fragments he drew out by the urethra with the guidance of the finger and forceps, the ligature shown. The natural explanation of how the ligature got into the bladder would be that there was some inflammatory disturbance around the pedicle, but if such were present it would suppose some evidence of pain, but the only pain complained of was that already mentioned.—Dr. Robert J. Rowlette read, for Dr. Richard J. Kinkead and himself, a paper entitled, "A Case of Labour Obstructed by Fibroid Tumour: Red Degeneration of the Tumour." The patient, a multipara, was admitted to the County Galway Hospital, having been 30 hours in labour; a globular tumour, four inches in diameter, was presenting at the vulva, apparently springing from the anterior lip of the os. As the tumour was very vascular Dr. Kinkead decided to deliver the patient before removing the tumour. Drawing the latter down and forward he applied forceps and extracted a living child. When the placenta came away he cut the pedicle of the tumour with an écarateur. The patient left the hospital quite well on the thirteenth day. The tumour was a typical example of "red degeneration," showing necrosis and congestion. The condition was comparatively rare and was in gestation. The condition was associated with pregnancy. It usually gave rise to marked constitutional symptoms, such as pain, weakness, wasting, and gastric disturbances. Dr. Rowlette believed that the staining was due to a diffusion of the blood pigment consequent on a sudden necrosis of a congested tumour.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 2nd, Mr. T. Geraty being in the chair.—Dr. J. S. Bolton read a paper on the Treatment of Prostatic Congestion by Electrical Methods. In it he pointed out that although the functions of the prostate and its secretion were still imperfectly understood it might be taken as established that (1) urgent symptoms in cases of this sort were attributable to congestion in and about the prostatic urethra, and (2) although actual enlargement, whether glandular or fibrous, might exist in late middle life, the ultimate failure properly to empty the bladder depended on the loss of tone in the muscle-fibres common in old age. Dr. Bolton then related the case of a man, aged 60 years, who had suffered from retention, with a good deal of anal congestion and a foul and turbid condition of the urine. Treatment over several weeks with high-frequency currents applied to the prostate per rectum led to a marked relief of all the urgent symptoms as well as a return of the urine to a healthy state. Later x rays were on three occasions applied to the perineum and scrotum and this produced a considerable shrinkage in size of a large hydrocele which had been in evidence for some years. In a second case, that of a man, aged 54 years, the same conditions obtained, while the pain and frequent micturition had led to a thorough nervous breakdown. In this case also treatment by high-frequency currents was followed by a complete restoration of health and vigour so that the patient was able to return to his work in a tropical climate. The benefit conferred by such treatment appeared to be connected directly with the marked improvement of the pelvic circulation induced thereby.—Mr. Geraty, Mr. W. Morley Willis, Mr. R. G. Hogarth, Dr. W. Tibbles, and Mr. R. E. P. Squibbs discussed the subject and Dr. Bolton replied.—Mr. Hogarth and Miss E. M. Henwood communicated a paper on the case of a woman, aged 56 years, who came under treatment for Extensive Ulceration of the Rectum. The patient had had one severe attack of dysentery 20 years earlier and a second two years before the present illness. When seen by Mr. Hogarth she had been for some weeks in a most distressing condition. She was greatly emaciated, with a weak pulse of 120 and general abdominal pain, and there was continual tenesmus, with the passage of mucus, pus, and blood. Owing to the failure of medicinal and dietetic treatment colotomy was performed on the left side and the bowel below the aperture was kept entirely free from faecal matters and irrigated daily with boric acid solution for about six weeks. Immediately after the operation her condition was for some days exceedingly precarious, as troublesome vomiting set in and femoral thrombosis occurred in both legs. Valuable assistance in the case was given at this stage by Miss A. M. le Pelley and recovery took place. Five months after the original operation a second one to close the opening into the bowel was undertaken and this was improved by a further operation three months later. When seen less than a month ago, and 18 months after the original operation, the patient was in perfect health, had gained considerably in weight, and the rectum had returned to a thoroughly normal condition.—Mr. A. R. Tweedie, Mr. Willis, and Dr. Bolton discussed the case and Mr. Hogarth and Miss Henwood replied.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Jan. 4th, Dr. J. R. T. Conner, the President, being in the chair.—Dr. W. Langdon Brown showed the following pathological specimens: 1. The Brain of a man, aged 25 years, who after an attack of influenza developed tingling and numbness of the right hand, loss of memory, headache, vomiting, early optic neuritis, and subsequently right facial paralysis. A tumour in the left frontal lobe was diagnosed but trephining over that region revealed none. A hernia cerebri developed which the patient infected and he died from meningitis. Post mortem a cystic cartilaginous tumour was found situated in the left occipital lobe. 2. The Heart of a man, aged 46 years, who died from gonococcal endocarditis. When admitted to hospital the patient had a high temperature and marked mitral stenosis; he had previously had pneumonia and an attack of hæmaturia. Infective endocarditis was diagnosed and a blood culture showed gonococci. Post mortem both mitral and aortic valves were narrowed, puckered, and had vegetations on them. There was also acute nephritis which accounted for the hæmaturia. 3. A series of specimens showing hæmorrhage into, and new growths of, the suprarenal gland.

Reviews and Notices of Books.

New Serum-Therapy. By D. MONTGOMERIE PATON, L.R.C.S., L.R.O.P. Edin. London: Baillière, Tindall, and Cox. 1906. Pp. 311. Price 6s. net.

IMPRESSED by the results reported by certain observers from the administration of antidiphtheritic serum by the mouth not only in diphtheria but in other diseases, Mr. Paton during the past eight years has subjected the matter to clinical and experimental study in the course of which we are told that he has employed 3333 ounces of antidiphtheritic serum and 40 gallons of simple plasma from the horse, the sheep, and the ox. His results are given in the book before us, which contains a description of the methods adopted, a series of "clinical papers" on various diseases and pathological conditions in which he has tried the use of the serums, and a theory of natural immunity which he has elaborated to explain his results.

Mr. Paton maintains that antidiphtheritic serum orally administered is practically a specific for septic infections, whether primary or occurring as complications of other morbid processes or infections, while simple plasma—that is plasma from a normal animal—is useful in cases of deficient nutrition from various causes, such as over-lactation and anemia, and also in some cases of tuberculosis. The antidiphtheritic serums used were specially prepared for Mr. Paton by a firm of druggists, one being described as a low potency serum, containing 6000 units to the ounce, and the other, called "special" serum, being prepared by the use of diphtheria cultures grown on a 25 per cent. aqueous solution of normal horse serum. The serum obtained from the horse after inoculation with such a culture is described as having greater "antiproteolytic power" and as being more effective in cases of chronic suppuration. Both serums are given in doses of one drachm diluted to half an ounce with water, the dose being repeated hourly or half-hourly for three or four doses and then every two or four hours as the course of the case may require. So marked are the results as recorded by Mr. Paton that it is difficult not to suppose that his enthusiasm has led him to take a highly roseate view of the effects obtained by the measures which he recommends; at the same time it must be admitted that he records some of his failures as well as his successes, and that he is careful to point out those conditions in which he has found it unavailing, such as pneumonia, gonorrhœa, syphilis, malaria, and locomotor ataxy.

Space does not permit of even an enumeration of the various conditions in which the antidiphtheritic serums and simple plasma have proved of value in Mr. Paton's hands; broadly speaking, they may be classed as septic infections, simple and traumatic inflammations, and various conditions of malnutrition and anæmia. The explanation of the efficacy of the serums suggested by Mr. Paton is that every tissue has a capacity for nutrition, repair, and maintenance of function which may be called tissue tone. This condition or capacity becomes resistance to infection or tissue resistance when it is capable of carrying on the function of the tissue unimpaired in the presence of an infection. Further, this tissue resistance is the fundamental factor in immunity, antitoxins and antibacterial substances being adjuvants. The oral use of plasma from an animal is supposed to convey to the patient the elements elaborated by the animal to produce in its tissues the reactions necessary for the maintenance of the normal tissue tone and to stimulate similar reactions in the patient. Antidiphtheritic serum is assumed to contain a substance which acts upon the involuntary muscle of the body antagonising the depressant actions the products of infective organisms.

another resisting the digestive action of septic organisms distinguished as the antiproteolytic element, and a third leading to increased leucocyte production. By these substances the beneficial effects of the oral exhibition of serum are explained and not by the antitoxin it contains, which is generally believed not to be absorbed in any quantity when the serum is given by the mouth.

Without actual trial it is, of course, impossible, to estimate the value of Mr. Paton's results but as he gives his methods in detail there should be no difficulty in putting them to the test and if in other hands they give only a tithe of the good results claimed for them in this book we shall welcome a valuable addition to our means of treating a group of troublesome disorders. It must be confessed, however, that although illustrative cases are given showing benefit or relief in an extraordinary variety of conditions no actual statistics are given, while in some instances the number of cases has admittedly been as few as two or three. Again, in many cases the conditions were those of chronic disease and the improvement temporary, an association which not infrequently occurs after the administration of fresh remedies in such conditions but not necessarily as a direct result. Again, in appendicitis Mr. Paton maintains that the serum, if given before the formation of pus, "in almost all cases so raises the resistance that the process is quickly moderated and recovery follows." Such a conclusion it would be difficult to accept in a disease which so frequently subsides without suppuration, except after its trial in a very large number of cases. The same criticism applies to other conditions in which it has been tried in only a very few cases, such as acute nephritis, meningitis, and otitis. None the less, the improvement recorded in many of the cases is suggestive and the method is worth a trial but without more extended investigation it is impossible at present to appraise its value.

Pulmonary Phthisis: its Diagnosis, Prognosis, and Treatment. By H. HYSLOP THOMSON, M.D. Glasg., Visiting Physician to the Consumption Sanatorium of Scotland, Bridge of Weir, N.B. London: John Bale, Sons, and Danielsson, Limited. 1906. Pp. 188. Price 5s. net.

THE aim of this little book is to "provide a short and concise account of pulmonary phthisis and be of some help to the general practitioner in the diagnosis, prognosis, and treatment of the disease." It embodies the author's experience gained during five years' connexion with the sanatorium at Bridge of Weir, a period of time which, we may venture to suggest, does not necessarily qualify a writer as an authority on all aspects of the disease in question, but which affords a respectable basis for many observations of value. The first section of the book deals with the diagnosis of pulmonary tuberculosis, as we think the condition is better called, the word phthisis being banished except as a convenient abbreviation for purposes of conversation or note-taking. This section is, perhaps, the weakest in the book, the author scarcely seeming at times to appreciate the real extent of the difficulties presented in recognising the early stages of the disease, while not a little of the advice given appears to be second-hand. The statements themselves are unexceptionable but we doubt whether they will afford any great aid to the practitioner in difficulties; in truth, he must gain his experience for himself or take the advice of those who have done so. The second section deals with prognosis and here we meet with more evidence of the author's own experience and respect his dicta accordingly. As a point of interest we note his view that the occurrence of pyorrhoea alveolaris in the tuberculous patient is of evil omen. The third section is devoted to treatment and here again much useful advice is given as to general and symptomatic measures. Of interest is the author's observation that harm rather than good resulted in the one and only case in which he tried amy-

nitrite for hæmoptysis. We doubt whether there is any special merit in forbidding tuberculous patients in sanatoriums the use of hats. The last chapter of the book deals with tuberculosis in children. We fully endorse the author's regret at the absence of organised effort in this country to provide accommodation for the open-air treatment of pulmonary tuberculosis in the young; indeed, the provision for all forms of tuberculosis in children is sadly inadequate. A more careful revision of the proofs of the book would have removed some grammatical errors, such as "the presence of adventitious sounds are of greater import," "resume the *statu quo ante*," and a few others. We are grateful to the publishers for the rough surface of the paper employed, which is a welcome relief after the highly glazed pages of so many modern books.

The Practical Medicine Series, comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the general editorial charge of GUSTAVUS P. HEAD, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume III, on the Eye, Ear, Nose, and Throat. Edited by CASEY A. WOOD, O.M., M.D., D.C.L.; ALBERT H. ANDREWS, M.D.; and GUSTAVUS P. HEAD, M.D. Series 1906. Chicago: The Year Book Publishers. Pp. 268. Price 6s.

THIS valuable compendium of papers which have been written during the past 12 months on these special subjects has been very carefully compiled by the editors. The papers are, however, somewhat unequal in value. The first 142 pages, which are devoted to the eye and its diseases, are of a more generally worldwide origin than the other two sections, in which the tendency appears to be rather to rely on the journals especially devoted to diseases of the ear, nose, and throat. We think that if the editors could arrange with one or more authorities in each specialty in foreign countries for the transmission of all papers bearing on their specialty worthy of record the result might be a work of such value that no thoughtful worker could dispense with it. However, as things are, the only annual record (in book form) in our language of the work done in these departments is to be found in the *Practical Medicine Series*, and the specialties dealt with owe the editors a debt of gratitude for their energetic and painstaking work.

LIBRARY TABLE.

Aequanimitas. By Professor WILLIAM OSLER, M.D., F.R.S. Second edition, with three additional addresses. London: H. K. Lewis. 1906. Pp. 475. Price 8s.—We reviewed the first edition of Professor Osler's delightful volume of essays in THE LANCET of Dec. 24th, 1904. This, the second edition, besides the essays contained in the first, includes three valedictory addresses delivered before leaving America, one of these being that entitled "The Fixed Period," which created such an excitement at the time of its delivery on account of Professor Osler's ironical suggestion concerning persons over 60 years of age. The closing essay of the book, entitled "Unity, Peace, and Concord," is written with all the breadth of view and the beauty of style which make Professor Osler's writings so characteristic and so valuable, and as the *envoi* to the book we have the remarks of Professor Osler at the farewell dinner given to him by the profession of the United States and of Canada in New York on May 20th, 1905. In this Professor Osler gives his British readers a glimpse at his life in Canada and the United States, and upon reading it we realise more than ever the loss which the United States have sustained and the enormous gain to Oxford which the passage of William Osler from one to the other has brought about.

The Management of a Plague Epidemic. By E. F. GORDON TUCKER, Captain I.M.S. Calcutta: Thacker, Spink, and Co. 1906. Pp. 30. Rs.1.8.—The principles laid down in

this work concerning the management of a plague epidemic are founded on a paper by the author which appeared in *Indian Public Health*. They are published with the view of giving some definite and precise instructions to the medical or civil officer who finds himself in charge of a town or district threatened with plague; such a position is very different in India from what it would be in a European country, owing to the racial and religious prejudices of the people and the difficulty of persuading them to adopt the necessary measures. The author begins by describing the stages of a plague epidemic. As regards the primary infecting agent he places in the order of their importance the following: (1) infected human new arrivals; (2) infected clothing; (3) infected merchandise; and (4) infected rats. The crucial point in Captain Tucker's management is to work on the supposition that a plague epidemic results from a temporary soil infection and therefore to endeavour to educate the inhabitants of any given town or city up to the point of accepting reasonable evacuation of areas in plague seasons. The methods to be employed in evacuation for plague will appeal to all who have had experience in the East as remarkably reasonable and in addition they are of such a nature as not to excite any religious or racial animosity. This little work is likely to be of much assistance to those engaged in plague districts.

A History of Dancing. By REGINALD ST. JOHNSTON, M.R.C.S. Eng., L.R.C.P. Lond. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1906.—Mr. St. Johnston's title is somewhat misleading and, indeed, it is impossible to compress a history of dancing, which is probably the most primitive way of expressing emotion, within the compass of 194 small pages. However, he has given us some interesting notes upon the subject. For instance, in Chapter II., which deals with dancing as a religious ceremony, he omits all mention of the solemn dance still held in the Cathedral of Seville on the Feasts of Corpus Christi and the Assumption, though he mentions that "right up to the middle of the eighteenth century there were traces of religious dances in cathedrals in Spain." At p. 49 he gives an account by an eyewitness of a Morris dance danced in Cheltenham about 40 years ago. A medical man informs us that more recently than this—namely, in 1878—he saw a Morris dance danced in Oxford; the exact date he cannot remember, but it was either just before or just after the day upon which the *Eurydice* foundered in the Channel (March 24th, 1878). The dancers, as in the Cheltenham dance, were dressed in knee-breeches, white shirts with sleeves tied up with ribbons, and carried short sticks. The choragus had a fox's brush attached to his hat and the hats were of a curious shape, something like a hunting cap. Mr. St. Johnston concludes his book with some accounts of modern dancers which are often imperfect, and modern theatre-goers would not acquiesce in the dismissal of the accomplished Mlle. Genée in three lines. The most interesting thing in the book to us is a reproduction of a delightful picture from an early copy of "The Pilgrim's Progress" showing a dance of joy of the pilgrims at the overthrow of Doubting Castle.

Annual Report of the Executive Medical Officer, Municipality of Bombay, for 1905. Pp. 93.—In his annual report Dr. N. H. Choksy deals with the deficient rainfall which occurred in Bombay again in 1905 as in the previous year. This, however, was not local but general over almost every collectorate and Presidency in India, although there were instances of excessive rainfall in places. Evil effects are to be feared from this deficiency during the next hot season, for refugees owing to famine will probably be flocking in numbers to the city, causing much overcrowding. The attitude of the vaccination department is entered into and the question of the somewhat large number of unregistered births is discussed. The annual

death-rate was 61·54 per 1000, against 54·99 in the previous year; excluding the mortality due to plague it was 43·25 per 1000. The increase in the year's rate of mortality was chiefly due to small-pox, measles, plague, fevers, and diseases of the respiratory system. The plague mortality commenced to rise from January and kept its high rate till the end of June, when it began to decline, being very low from October to December. The number of attacks and deaths from this disease registered during the year was respectively 16,308 and 14,193, as against 15,488 and 13,538 during the previous year. There was an epidemic of small-pox during the cold season in Bombay, the advent of the abnormal cold weather being very favourable to its dissemination. Still further, it threatened to spread through the city and to affect all communities alike. The divisional health officers and the district registrars and their staffs took vigorous measures to arrest the progress of the epidemic and to press vaccination by issuing instructions as to vaccination and revaccination and leaflets informing the public of the addresses of ambulances for the removal of patients suffering from small-pox. The mortality among the cases removed to the small-pox hospital was 25·66 per cent. as contrasted with that of those not removed, which was 62·81 per cent. A section of the report deals comprehensively with the subject of plague administration, especially with regard to the systematic examination of rats. Much valuable information has been gathered as to the relation of plague in rats to plague in man. Since the examination began in July the ratio of plague-infected rats to the total number daily collected has risen from 2 per cent. to 20 per cent. The rats were sent to the Farel Laboratory for examination, where bacteriological examination was made of every rat sent, and whenever a rat was found to be plague infected an intimation to that effect was at once sent to the place from which it was derived and also to the divisional health officer; the place was then disinfected. About 1600 rats were examined daily. The report states that it is too early as yet to form any conclusion from the inquiries hitherto made. As regards the effect of the serum treatment in saving life there could be no doubt as to its being of greater efficacy than the ordinary treatment. This report is very creditable as regards the large amount of work that has evidently been performed during 1905 by the health authorities in Bombay.

School Hygiene and the Laws of Health: A Text-book for Teachers and Students in Training. By CHARLES PORTER, M.D. Edin., Barrister-at-Law, Middle Temple. With 119 illustrations. London, New York, and Bombay: Longmans, Green, and Co. 1906. Pp. 313. Price 3s. 6d.—The matter upon which this book is founded formed the basis of a course of lectures delivered to the teachers acting under the Education Committee of Sheffield and the students of the Sheffield Training College. The idea of the education committee in arranging for the course of lectures was to afford the teachers an opportunity of acquiring such information as might assist them in protecting the health of school children. It was desired that the course might include not only instruction in what has been called the "laws of health," which the teachers might in turn impart to the children, but also hints on the manner of detecting diseases likely to be met with in schools. The lectures were largely modelled on the plans set out in the syllabus for the Royal Sanitary Institute examination in school hygiene; each system in the body was taken up in turn, the structure and functions of the organs composing it were considered, and the modes in which they might be affected by school conditions and diseases and how they were to be protected were described. In the first part of the book each system is treated of in a separate chapter. The second part deals with the school building and is largely an extension of the regulations of the Board of Education, 1905,

in connexion with school construction. In this part school furnishing, sanitation, ventilation, and such other subjects as could not well be discussed in the first part are considered. In Chapter XI., which deals with eyesight, the author has had the advantage of the advice of Mr. Simeon Snell, ophthalmic surgeon to the Royal Infirmary, Sheffield, and professor of ophthalmology in the University. One of the best portions of the book is the section which deals with the seating arrangements for the children. The proper seat is one that compels the pupil to sit upright with the head and trunk erect, with the work at the average near-point distance, with the thighs at right angles to the trunk and legs, and both feet flat upon the floor, not on foot-rests, at right angles to the legs. It would be well for all scholars if the adjustable seats and the Anglo-Swiss adjustable desk, or seats and desks of similar patterns, were introduced by compulsion. In many of our large public schools not only are the class-rooms badly lighted and ventilated but the forms and desks are so arranged as to permit boys to sit in a slouching manner during the hours of tuition and preparation; hence, in spite of cadet corps and gymnasiums, they often hold themselves badly. The book is an excellent manual; we wish that the head-masters and house-masters of our public schools were obliged to possess the knowledge which it contains. We look, however, in vain for any suggestions on the difficult subject of punishments for school-boys. At present, in some of our public schools, the cane applied over the nates or, what is worse, over the back indiscriminately, is used as the chief punishment both by the head-master and house-masters, with, we believe, disastrous results in many cases. The old form of birching for the graver offences is, in our opinion, less harmful in every way. We hope that Dr. Porter will add a chapter on the subject of school punishments should a second edition of his book be called for. The illustrations in the volume are good.

Plant Life. By HORACE F. JONES, F.O.S. London: Methuen and Co. 1906. Pp. 260. Price 3s. 6d.—The increasing attention which is being paid to nature-study in primary and secondary schools has resulted in the production of many books the object of which is to educate the observational powers of pupils and to stimulate their interest in the world around them. The present volume belongs to this class of publication. In designing a course of studies in plant life the author has had in mind the difficulties which beset the teacher owing to the limited time at his disposal for this kind of teaching as a special subject and also the obvious restrictions imposed by seasonal and climatic conditions generally. While clearly recognising that the study of plant life ought to be made in natural surroundings—in fields and country lanes—the author has endeavoured to minimise the inevitable restricted conditions of nature-study in schools by calling to his aid small cultivated pieces of ground, a few flower-pots, and some apparatus of a quite simple kind. The book is divided into two parts, the first dealing with plant life in the garden and the second with plant life in the school. Commencing in Part I with a study of the twig and the fall of the leaf, the author next discusses bulbs and tubers, insect visits, fertilisation, and the various devices of nature for the preservation of species and adaptation to environment, closing with an account of the grass family and ferns. In Part II. various experiments in connexion with the physical, chemical, and physiological functions of plants are indicated. An appendix gives some valuable information as to the best time of sowing seeds, transplanting seedlings and plants, and the means and cost of procuring apparatus. A feature of the excellent illustrations is that they have been so drawn as to be copied easily on a black-board. We are glad to see the suggestion that teachers in town schools should obtain and plant, where possible, specimens of common wild flowers. It is a matter for regret

that so few people in these days know the names of many of the most common of our wayside flowers and anything that can be done to foster a knowledge of our native flora is most desirable. The book is an eminently practical one and should form a welcome addition to a teacher's library. Though it may not be found possible in every school to teachers to work with their pupils through the whole course many useful suggestions and hints for object lessons in nature-study can be obtained from the book.

JOURNALS AND MAGAZINES.

Caledonian Medical Journal.—The opening article of the January number contains the clinical lecture by Dr. Willis Russell on Gastric and Duodenal Ulcer, which we publish in this issue of THE LANCET. Dr. W. A. Mackintosh of Stirling the President of the Caledonian Medical Society, describes a Gaelic Medical MS. attributed to the fifteenth century and now in the library of the University of Edinburgh; the part of it consists of translations from the "*Lilium Medicinæ*" of Bernard Gordon of Montpellier in France. The Rev. Hugh MacCallum of Blair Atholl contributes an interesting account of the outlying island of St. Kilda where he once lived for a year as a teacher. Colonel Kenneth Macleod, I.M.S. (retired), formerly editor of the *India Medical Gazette*, relates an unpleasant experience into which journalistic duties led him—namely, a charge of criminally defaming another officer of the Indian Medical Service. At the trial Colonel Macleod was sentenced to a fine of Rs. 300 or a month's imprisonment but on appeal the Chief Justice of the High Court quashed the sentence. Dr. R. C. MacLagar of Edinburgh, in a paper on Folklore, discusses the origin and etymology of the words Duncan and Duncanson; some idea of his arguments may be formed from the circumstance that he quotes without comment the suggestion that "donkey, the animal name, took its origin from some Duncan or other."

The Edinburgh Medical Journal.—The December number opens with an address by Sir Dyce Duckworth on the Dignity of Medicine in which he notes that "the relations between physicians and intelligent patients are hardly as satisfactory now as they were wont to be" and attributes some part at least in the change to defective general education in medical men. Dr. H. G. Melville writes of Primary Broncho-pneumonia in Adults which he considers to be by no means so rare as text-books would seem to imply, the difference between it and lobar pneumonia depending on the varying virulence of the causal organism, and Dr. J. Hally Meikle records some observations on Diphtheria Bacilli in the Throats of Convalescents and speaks in favour of careful local antiseptics. Mr. H. de Merio praises santal for the internal treatment of gonorrhoea.

The Scottish Medical and Surgical Journal.—In the December number of this journal Dr. G. Lovell Gulland writes of Blood Examinations in General Practice and notes incidentally that slight cases of pernicious anaemia are more common than is often supposed, he himself having seen 30 new cases in the last year. Dr. J. W. Simpson recommends the use of preparations of thyroid gland in infantile marasmus and Dr. Edwin Bramwell and Dr. Arthur H. H. Sinclair emphasise the importance of Ophthalmoplegia Interna Unilateralis (surely it should be unilateralis) as a symptom having the same significance as the Argyll-Robertson pupil.

BRISTOL DISPENSARY.—The annual report of the Bristol Dispensary for 1906, which has just been issued, states that during the year 10,323 patients were treated, being an increase of 282 compared with 1905. The financial statement was satisfactory and showed that during the year a legacy of £1424 had been received from the executors of the late Rev. S. Tebbs.

THE LANCET.

LONDON: SATURDAY, JANUARY 12, 1907.

The Benevolent Agencies of the Profession.

THE epitome of cases relieved by the British Medical Benevolent Fund which we print from time to time, and the voting papers issued by the Royal Medical Foundation attached to Epsom College serve to keep before the profession two unpleasant facts—namely, that many members fall upon evil times owing to advanced age or to permanent incapacity, and that when death calls them from a life of ceaseless toil those who are near and dear are too often left poorly provided for and in many cases absolutely dependent upon the charity of friends. To read the brief accounts of cases relieved by these two important medical charities is painful in the extreme, and were it not for the fact that they forcibly remind medical men of their duties to themselves and to their fellow members the publication of such lists would hardly be desirable. From the constant appeals which emanate from the treasurers of both institutions, and in view of the comparatively small grants which are made by the British Medical Benevolent Fund, we are forced to come to the conclusion that there is an almost culpable lack of interest in the benevolent agencies of the profession. This conclusion is supported by two facts. In the first place, out of the 19 candidates for pensionerships from the Epsom College Foundation at the last election in only two instances had the college been supported by the husband or candidate, and the parents of only five out of the 30 candidates for foundation scholarships had contributed to the college in their better days. When we remember that considerable privileges are given, under the by-laws of the college, to candidates whose families have been contributors, thus enabling the foundation to be looked upon as somewhat in the nature of a provident society, it is surprising that comparatively so few medical men avail themselves of the advantages offered. In the second place, most of the leading provincial medical benevolent societies have been established over 60 years and some for over a century, so that we apparently lack the foresight and perseverance of our forefathers. We do not overlook the fact that there are considerable invested funds in connexion with both the London institutions to which we have referred for the purpose of giving pensions, but inquiry would probably show that these are the result of benefactions on the part of deceased medical men and others and are not the savings out of the contributions from members of the profession in practice.

It is universally granted that professional men as a rule are not business-like, and members of our own profession would hardly claim to be excepted from the rule. This, then, is probably the reason that there is so lamentable a lack of forethought on the part of medical men generally, with the

result that the different agencies for rendering help in times of distress are not sufficiently known or fully appreciated. We have frequently drawn attention to the Society for the Relief of Widows and Orphans of Medical Men, the invested funds of which amount to close upon £100,000. Any qualified practitioner living within a radius of 20 miles from Charing Cross may be proposed as a member, the annual subscription being only two guineas, yet, though the names of 6500 medical men appear in the London part of the Medical Directory, there are only 296 members of this society in all. The benefits to be obtained by widows and orphans are far greater than those given by any insurance society, as two or three instances will show. A widow received for herself and family the sum of £2272, though her husband had paid only £18 18s. in subscriptions; three widows received an average of £700 each, whilst another received for herself and family £1654. Yet in spite of the repeated notices which appear in our columns as to the work carried on by the society so small a percentage of medical men eligible to be proposed as cardinals avail themselves of the advantages of this society. There are also several provincial medical charities which are doing much good and which would be able to extend their work materially if they were but better endowed. The Birmingham Medical Benevolent Society carries on a useful work and in two instances £15 15s. paid in subscriptions were returned in grants amounting to £686 and £1247 respectively. The West Riding of Yorkshire Medical Charitable Society is well supported but it deserves to be helped by every medical man in that wealthy and extensive county. The Royal Medical Benevolent Fund Society of Ireland does good work but its honorary local secretaries and the council constantly complain of the lack of support. Benevolent societies also exist for Devon, Essex, Hertfordshire, Kent, Lincolnshire, Surrey, and Sussex, the last-mentioned having been established only two years ago. The Surrey Medical Benevolent Society is deservedly successful and possesses four presentations to Epsom College, the holders being admitted at a very moderate fee, but medical men in that county none the less put off the duty of joining the society. It must be recollected that in the cases of all local societies help is given with much less routine than when societies are dealing with strangers. It may be said that local societies are not well supported because subscriptions go to such general institutions as the British Medical Benevolent Fund, which disburses large sums annually in grants and pensions, and the Epsom College Foundation, which gives 50 pensions of £30 a year and boards, clothes, and educates free of charge 50 foundation scholars, but a glance at the lists of subscribers to both these charities will show that this is not a sound argument. If any page be taken from either list and the names of laymen, of livery companies and commercial firms be eliminated, and the remaining names be compared with the Medical Register, it will be seen that the support given by the profession is paltry in the extreme.

What is urgently wanted in the case of our benevolent agencies is not the generous support of a few conscientious men but the assistance, in however small a way, of all members of the profession. Every medical man entirely dependent upon his profession who is living within 20 miles of Charing Cross should look upon it as a duty to join the Society for the Relief of Widows

and Orphans of Medical Men; those living in counties where medical benevolent societies exist ought to be only too glad to avail themselves of the opportunities provided for them through the efforts of their far-sighted forefathers, so that if the hand of misfortune should fall upon them or their families timely help will be forthcoming more as a right than as a favour; and those medical men who possess the gift of business capacity should endeavour to institute local benevolent societies in counties where at present none exist. With loyal support such societies would not only be able to provide annuities and grants, but, as in the case of the Surrey Medical Benevolent Society, should be able to arrange for boys to enter Epsom College on favourable terms. In conclusion, the two great London charities, the Royal Medical Foundation of Epsom College and the British Medical Benevolent Fund, ought to receive the support of every medical man who can afford to subscribe half-a-guinea or 5s. annually, for even if county associations give pensions and grants to their members the annuities from these two charities would supplement the local aid, apart from being the sole assistance in the case of numerous applicants who otherwise would not be helped. As for the work done by the Epsom College in maintaining 50 foundation scholars, thus enabling boys in many cases to regain the position lost through the premature death or permanent incapacity of their fathers, some of our readers will frankly confess that they practically owe all that they possess to the help rendered by the college.

We may, in conclusion, refer briefly to the work of THE LANCET Relief Fund, the annual report of the Almoners of which, with the balance-sheet audited by the veteran Sir HENRY PITMAN, now but six months away from the hundredth anniversary of his birthday, appears in this issue. The proprietors of THE LANCET have since 1889 placed £300 to the credit of this Fund upon the first day of each year (making in all a total of £5700 contributed by them since its commencement) and have left the distribution, with the consent of the Councils of the Royal College of Physicians of London, of the Royal College of Surgeons of England, and of the General Medical Council, in the hands of the Presidents of those bodies, who have in their different personalities invariably consented to be associated with them as Almoners. Last year 33 cases were relieved, at a cost of £460 7s. 9d. The Fund is designed to meet cases of sudden emergency in a way that the usual benevolent agency cannot effect, and information derived during its administration has proved over and over again to us the value of its work.

An Editor's Responsibility.

A VERY important prosecution was brought to a satisfactory conclusion on Dec. 19th, 1906, when the Court for the Consideration of Crown Cases Reserved affirmed the conviction of EDWARD DE MARNY, editor of *Judy*, which took place some weeks before at the Old Bailey. On Tuesday last, Jan. 8th, DE MARNY surrendered to his bail and was sentenced to two months' imprisonment in the second division. The charge arose out of the publication by the defendant in his paper of a number of advertisements of indecent books and photographs, but the importance of the case from our point of

view lies in its bearing upon advertisements of abortifacients and of quack medicines sold as such. The conviction of DE MARNY should result in the encouragement of the police in taking proceedings in respect of a grossly mischievous laxity into which those responsible for many newspapers and magazines constantly fall. The precise offences with which DE MARNY was charged were stated in various counts of an indictment which set forth under alternative aspects that he aided and abetted in the dissemination of indecent matter by causing and procuring to be sold the books and photographs described, and by causing and procuring them to be sent by post. A page of *Judy* containing advertisements lies before us and constitutes a document of which it might well be said that if the law were powerless to deal with it the sooner the legislature turned its attention to strengthening the law the better. The page in question is from the issue of Oct. 20th, 1906, and contains 19 advertisements, of which six refer to books and photographs in terms which leave no doubt as to the character of the literature offered, and the rest present the claim to public support of "female pills," of "cures for irregularities," of "cures" for "exhausted vitality and all special diseases and weaknesses of man," and of "rubber goods." The most prominent advertisement in the page, occupying a whole column, opens with the offer at 1s. 3d. post free of a book entitled "Marriage and Mysteries," for which its publisher, whose address is at Nottingham, claims the distinction that it has been "twice seized by the police." Some of the advertisements of photographs are those of dealers with addresses abroad, others of dealers at home; whether, in fact, these all relate to indecent publications we are not aware but they are so worded that they would obviously suggest an opportunity for the purchase of indecent pictures to persons in search of such. The other advertisements referred to are of the usual kind. Another page of the same issue before us contains yet more advertisements of like character to those described, and as the number of the paper which we have obtained is of a date subsequent to the commencement of proceedings against its editor we may safely infer that the advertisements for which he will now suffer imprisonment did not fall short of those which we have examined.

In addition to the advertisements which he inserted being themselves absolutely disgusting in their barefaced audacity, he had been warned distinctly by the police of the nature of the goods which the vendors sought to make known with his connivance and assistance, and that this had some effect in rendering his conviction inevitable may safely be inferred. The police supplied evidence of the actual nature of the goods advertised, producing photographs and books which they had obtained by writing to the addresses given. The points left to the consideration of the jury by the Common Serjeant who tried the case at the Old Bailey may be noted as indicating what would have to be proved should prosecutions take place in respect of other advertisements as has been suggested above. He directed them to convict should they be satisfied (1) that the books and photographs received by the police from the advertisers were in fact obscene; (2) that the defendant knew when he printed the advertisements that the things

advertised were obscene; and (3) that the advertisements brought about the sale and transmission by post of the books. He further laid down that it was not necessary that the defendant should be proved to have known in detail the actual subjects of the books and photographs, and that the jury, in estimating his knowledge, might take into account the warnings given to him by the police, the nature of the advertisements under consideration, and the nature of the other advertisements in the same issue of the defendant's paper. The points of law submitted to the Court for the consideration of Crown Cases Reserved were, firstly, that as the vendors of indecent matter lived and carried out their transactions beyond the jurisdiction of the court there could have been no conviction of them as principals, and that as a matter of law there could be no conviction for "aiding and abetting" principals who could not themselves be convicted as such. Secondly, it was argued that by publishing advertisements the defendant could not be deemed to procure the publication of the obscene matter any more than a sandwichman could be said to procure a theatrical performance by carrying a poster relating to it through the streets. Lord ALVERSTONE, however, who delivered a judgment with which the four judges who sat with him concurred, declined to accept these propositions and held that the Common Serjeant had directed the jury rightly in accordance with the precedents contained in cases already decided. His lordship pointed out that the defendant had for his own profit inserted in his newspaper advertisements which informed people where certain matter could be obtained, and it was found as a fact in the case that he knew that the matter advertised was of an indecent character and that if they were at liberty to draw any conclusion from the advertisements themselves there could be no doubt that he knew. His lordship added with emphasis that, in his opinion, it would be a lamentable thing if the law were not strong enough to deal with such a case.

DE MARNY therefore goes to prison with the full assurance that his punishment is strictly justified by the legal aspect of his offence and that all right-minded citizens must feel that it is richly deserved from the point of view of those who consider the moral welfare of the community. His trial has established the fact that a jury will hold that the editor of a newspaper knows as well as his readers do the ordinary import of the advertisements which he or the proprietor of the journal is paid to publish and that the law allows him to be credited with that knowledge. After all there is no particular hardship involved in this. It is not necessary that he should exercise an extraordinary amount of intelligence or of vigilance, and he is not likely to be charged with an offence where an isolated insertion of objectionable matter has been due to a mistake. Traders who sell indecent pictures and literature and those of the other class to which we have referred who deal in quack concoctions, which they sell as abortifacients, have to inform those members of the community for whom they cater of the nature of the goods that they hold for sale. In order to do this it is essential for them that they should address a circle of readers as wide as possible, and that they should do so in such plain and simple language

that persons not usually of a very intelligent class may understand at a glance what is offered. Their advertisements are written with this object, and that they attain it is shown by the fact that whenever an abortionist is arrested and his place of business is inspected by the police it is found that the correspondence elicited has been enormous. Indeed, the number of these advertisements and their obvious costliness afford by themselves ample evidence of the prosperous trade which they enable the quack to carry on. Editors and proprietors of newspapers are usually credited with a certain amount of intelligence and acuteness of perception, as well as with some knowledge of the world. In order to hold them responsible as knowing what they advertise a jury must tellere them to be as capable of understanding certain phrases and expressions of no particular obscurity as the servant girls and others of similar educational attainments to whom the matter in question is largely addressed. If certain advertisements now appearing in newspapers which could readily be named do not disappear before long we shall hope to see similar prosecutions to that of DE MARNY instituted, particularly in respect of abortifacients. Here the goods advertised are sold and bought with a view to the commission of felony and are used to endanger and to destroy human life, a matter which seems to demand police interference no less than the corruption of the young by the dissemination of lewd literature and pornographic photographs. We should like the prosecutions also, where possible, to have regard to the position of the proprietors of the offending journals. It is the proprietor, not the editor, whose purse is directly enriched by the money of advertisers. To some extent the proprietor is in the power of the editor, with whom the refusal of a doubtful advertisement must lie; but, on the other hand, the editor is in the hands of the proprietor who can order him to insert any particular advertisement or to send in his resignation.

"The Surgeon's Power of Life and Death."

DR. J. A. RIGBY has contributed to the December number of the *Independent Review* an article entitled "The Surgeon's Power of Life and Death," and has thereby stirred into enthusiasm the *gobe-mouches* of the local press of the district in which he resides, and has to our mind, presumably without the least intention, done a certain amount of damage to his profession. Dr. RIGBY informs the readers of the *Review* that "gradually, progressively, almost imperceptibly, there has of recent years arisen in our midst a new tribunal—endowed with the power of deciding questions of life and death," and that "there is no appeal whatever from its decisions, which are practically immutable and irresistible." He goes on to say, in words too numerous for precise quotation, that as soon as a man has obtained any medical qualification he is at once given in a vast number of cases the power of deciding whether a person consulting him shall be submitted to an operation "which may cost him his life or leave him seriously maimed or incapacitated for life. This terrible power of life and death is placed in the hands of an inexperienced youth, practically without any safeguard," and that when an operation has been performed

has been given by the operator, "there is an end of the matter." This is an extraordinary farrago to be put forward by a medical practitioner and the author goes on to illustrate and to support his position by an account of an "illegitimate and indefensible operation" which was performed, in spite of his opposition, by a "well-known operating surgeon," at the house of the patient, who was a blacksmith "suffering from a cancer affecting the parietes of the abdomen just over the region of the liver." The operator, we are told, has long been dead, and there is therefore no possibility of obtaining any version of the story which might remove its apparent contradictions and bring it into line with ordinary experience, but, even as it is told, it does not seem to us to reinforce Dr. RIGBY's contentions.

Dr. RIGBY divides operations into three classes: (1) the legitimate and defensible; (2) the illegitimate and indefensible; and (3) such as are on the borderland between the preceding; and he omits to point out to his lay audience that, even assuming his classification to be correct, the tendency of events is towards the constant removal of his second and third classes into the first. Such a removal, indeed, is in brief the history of surgery. A man of original mind sees the possibility of relieving some ailment by surgical means, but he does not at once perceive all the difficulties which may stand in the way of a successful issue. He tries, and perhaps accomplishes the operative procedure at which he aims, but he does not succeed in curing the patient. He tries again and succeeds. He compares the conditions of the first case with those of the second and by proceeding in this way he gradually learns to eliminate the cases which are unsuitable for operative treatment and to obviate the causes of death in those for which operations are performed. Such, for example, was precisely the history of ovariectomy. The discovery of an ovarian cyst was, before the operation for the condition was devised, a sentence of death, but the patient might look forward to an average respite of about four years, mostly years of suffering and of incapacity. The removal of the cyst, when first undertaken, was immediately fatal in about three cases out of five; and distinguished surgeons were of opinion that the operation, to use the words of Dr. RIGBY, was "illegitimate and indefensible." By patience and perseverance the difficulties were overcome, and when Sir SPENCER WELLS was able to chronicle a hundred consecutive cases without a single death the operation took its rank among the natural resources of surgery, no longer as a forlorn hope which might be offered but as an ordinary method of treatment, of the benefit of which it was not right that any patient should be deprived. Before this stage was fully reached we heard of a case in a provincial city in which a surgeon who was abreast of the knowledge of the day suggested that the operation should be performed. The friends desired that an elderly physician of the locality should be consulted. He came but altogether refused to sanction the operation. He did not, however, desire that the patient should be left untreated. "What I should do," he said, "would be to rub her belly with a little goose grease." The history of the operation for appendicitis, now every day performed successfully, is much the same as the history of ovariectomy, with the difference that

many cases of appendicitis would recover if treated by medical means alone. Notwithstanding this difference, there can be no doubt that the operation has greatly diminished both the general mortality arising from the condition and the duration of illness in cases which might have recovered under medical treatment alone. Its systematic performance could not be relinquished except at the cost of many lives.

Dr. RIGBY's assertion that the responsibility of deciding in a question of life and death is left, "in a vast number of cases," in "the hands of an inexperienced youth" is, amazing to us from a medical man's pen. An "inexperienced youth" does not attend a "vast number of cases" of any sort; and very few patients would accept his recommendation to be operated upon until it had been confirmed by practitioners of longer standing than his own. The regulations of most hospitals are such as to afford only limited opportunities of operating to the junior members of the surgical staff, and consultations are usually required before operations are undertaken. On the whole, in such matters the mental tendencies of the profession are, we think, decidedly conservative. In the early history of ovariectomy, while two or three men were working silently and strenuously to bring it to perfection, the general attitude of the profession was distinctly hostile. The first amputation at the hip-joint ever performed in England was done by Mr. ORTON, a general practitioner in a Nottinghamshire village, on a young man who had been sent home from the Nottingham Infirmary to die. Mr. ORTON asked the surgeons to the infirmary to be present and they came, but they declined to take the responsibility of rendering him any assistance and remained as passive spectators of his proceedings. Fifty years afterwards the patient followed the remains of Mr. ORTON to the grave, and an operation which Dr. RIGBY would, we fear, have denounced as unjustifiable was fully justified by its results.

As long as human nature is fallible, surgeons, like other men, will sometimes do what it would be better to omit and will sometimes omit what it would be better to do. But the path of duty in relation to the matters dealt with by Dr. RIGBY is not only perfectly plain but it is also perfectly well understood and systematically acted upon. It is unjustifiable to perform an operation which offers no reasonable prospect of success and, *pace* Dr. RIGBY, few surgeons would attempt such an one, even if it were only from regard to their own reputations. The death of a patient, and especially of an operation case, is often extremely injurious to a practitioner. It is equally unjustifiable to withhold from a patient a possible means of safety and of cure, or to depend upon "goose grease" when an operation is required. The plain duty of the surgeon, in every case, is to place the truth of the matter, so far as it is known to him, before the patient and the patient's friends, to suggest a consultation in cases as to which he is in doubt, and not to refuse to give a chance of life and of recovery, even when it may seem to him to be a slender one. As for the patient, if he chooses to place the issues of life and death in the hands of "an inexperienced youth" he has only himself to blame. The want of experience should be misleading. The alarm sounded by Dr. RIGBY appears to us to be a

false one; and we think his paper calculated to excite a prejudice against the medical profession, and against operating surgeons more especially, which the facts, far from justifying, are calculated entirely to remove.

Annotations.

"No gold snails."

THE VITAL STATISTICS OF LONDON IN 1906.

THE public health committee of the London County Council has just submitted the report of the medical officer of health of the county of London for 1906, and the report of the committee calls attention to the marked decline in the death-rate prevailing in recent years among the nearly five millions of persons residing within the county of London. We shall review Sir Shirley Murphy's report in full in subsequent issues of THE LANCET, but in the meantime it may not be without interest to supplement this report with a few facts relating to the health of London in the year 1906, derived from the Registrar-General's weekly and quarterly returns. The death-rate of the London population in 1906 was equal to 15.7 per 1000, against 16.6 and 15.6 in 1904 and 1905. As evidence of the remarkable improvement in the health of London during recent years it may be noted that during the last four decades of the nineteenth century the metropolitan death-rate was successively 24.4, 22.5, 20.5, and 19.6 per 1000, while the mean annual death-rate during the first six years of the present century has further declined to 16.5, showing a far more rapid rate of decrease than prevailed in any of the four preceding decades. That the London death-rate in three of the last six years should have fallen considerably below 16.0 per 1000 can only be regarded as a triumph of progressive sanitary administration and as confuting the alleged progressive physical degeneration. This evidence of sanitary progress should, however, act as a powerful incentive to further effort to combat the unquestionable degeneracy which still exists in many parts of the metropolis and which will be reflected in some of the local district death-rates, when they are available. For instance, in 1905 the corrected death-rate in the metropolitan boroughs ranged from 10.5 in Hampstead to 20.6 in Shoreditch, and there is little ground for supposing that the local rates for 1906 will not differ fully as widely. It is also eminently satisfactory to find that the rate of infantile mortality has recently, to some extent, shared in the general decline of the London death-rate. During last year the deaths of infants under one year of age were in the proportion of 133 per 1000 registered births, against 146 and 131 in 1904 and 1905. The mean rate of infantile mortality in London during the ten years 1891-1900 was equal to 160 per 1000, and considerably exceeded the mean rate during the preceding 50 years; the mean rate in the past six years of the current decade, 1901-6, has fallen, however, to 139 per 1000. It is true that this infantile death-rate last year slightly exceeded the rate for 1905, but it must be borne in mind that the meteorological conditions during last summer, of high temperature and exceptionally small rainfall, considerably increased the fatality of diarrhoea, which caused 3536 deaths in London in the summer quarter of 1906, against 2708 in the corresponding quarter of 1905. Due allowance for the effect of those unfavourable meteorological conditions fully accounts for the slight increase last year in the rate of infantile mortality compared with the still lower rate that prevailed in 1905. Notwithstanding this satisfactory recent

decline of infantile mortality in London there is still abundant proof of much waste of infant life in the metropolis. In 1905, for instance, when the general rate in London did not exceed 131 per 1000, the rate ranged upwards in the several metropolitan boroughs to 151 in Bethnal Green, 153 in Poplar, and 167 in Shoreditch. Public interest in this discreditable loss of infant life has been so thoroughly aroused by the recent National Conference on Infant Mortality that further reduction in the near future may be confidently anticipated in London as well as in those provincial towns in which the waste of infant life is still more conspicuous.

HOSPITALS AND THE PREVENTION OF DISEASE.

IN the first report of the Stepney Visitors' Association, a copy of which has been sent to us, there is a note under the above heading calling attention to neglected opportunities for the education of the public in the elements of hygiene. It is suggested that the resources of the great voluntary hospitals might be applied to measures directed to exterminate disease, in addition to those of the actual treatment with which they are at present mainly concerned. The outline of the scheme suggested may be given in the writer's own words: "It is submitted that the romance attached to hospitals and the faith of the public in the clinical economy within their walls afford a *prima facie* reason for the great success of any movement which had as its object the elementary education in the first principles of health and the prevention of preventable diseases, of district visitors, of parties of mothers, of members of artisans' clubs, and of classes of school children. General hygiene might be considered, with particular attention to such special subjects as tuberculosis, vaccination, diets for different ages, the abuse of alcohol, and first-aid to the injured." The writer proceeds to detail suggestions by which these objects might be carried out as follows: first that a series of "talks upon health topics" might be held for patients in hospital or convalescent home during convalescence; secondly, that parties of artisans and housewives gathered by social or religious workers should be instructed in the matters concerned in elementary hygiene and that children from public elementary schools might be brought periodically for part of their ordinary school work, while special opportunities might be afforded to accredited district visitors; and, thirdly, that co-operation with voluntary visiting associations should be secured by the hospital authorities in order to help in the carrying out of directions given to the out-patients at the hospitals. In the event of resistance or opposition to such proposals by hospital authorities on the ground that they are fulfilling their work in the treatment of the sick and in the education of medical students it is suggested that pressure should be brought to bear, through the executive of the great hospital funds, by the charitable public ear-marking their subscriptions for institutions carrying out these or similar functions. While we are in general sympathy with any movement likely to be effective in promoting a useful knowledge of the laws of health and of the prevention of disease, it may be questioned if such a scheme is practicable and whether the hospitals can be expected to do more than co-operate. The education of the public in such matters is surely the province of educational authorities and of the medical departments of local boards or borough councils. The hospitals were instituted for the treatment of disease and in this they have shown commendable real in keeping abreast of modern advances; indeed, in most cases of pioneering them, by which their resources have become taxed to the utmost, so that the expression "gigantic resources" used by the writer of this note is hardly felicitous. To carry out effectively the suggestions made would entail considerable labour and expense and would require a special organisation. On

the other hand, such work might well be carried out at certain selected hospitals in populous districts under the ægis of, and at the expense of, the local sanitary or health board.

ELECTRIC LIGHT IN MARYLEBONE.

SURGEONS undertaking to perform operations with the aid of artificial light within the limits of the metropolitan borough of Marylebone will do well to assure themselves that they are not wholly dependent upon the electric light supplied by the corporation. Twice during the past two months a considerable district in and around Oxford-street has been plunged into darkness suddenly and without warning after the lamps had been lighted for the evening in shops and houses. These incidents have been made public by the newspapers and have forced themselves upon the notice of those who witnessed them, but minor failures of current have been frequent since the council of the borough undertook to light it after internal discussions and dissensions as to the expediency of its so doing which will be fresh in the minds of all. What the immediate causes of individual cases of extinction of light may have been we are not concerned to inquire; such events are, however, very unusual in other parts of London and the area supplied by the Marylebone corporation contains a residential district largely inhabited by medical practitioners and dentists and also a great number of private hospitals and nursing homes. The winter is a season of fogs and darkness in London, when at other times than at night artificial light is absolutely necessary and when its sudden failure where patients are seriously ill or are actually undergoing operations may mean not only inconvenience and anxiety but danger to human life. Gas is rarely provided coextensively with electricity in private houses, at any rate, and in many of these where electricity has for some time been in use oil-lamps and candles have ceased to be kept ready or have practically disappeared. It is to be hoped that if any legal remedy is found to be in the hands of those deprived of their light in the recent cases mentioned it will be strenuously enforced on public as well as on private grounds, and that any liability there may be for the inconvenience and loss suffered by shopkeepers and others will be brought home to all who can be made responsible.

THE MEDICAL ART IN THE HOMERIC POEMS.

THE Homeric Epics, as many of our readers know, afford a large amount of evidence as to medical and surgical knowledge among the ancient Greeks, the *Iliad*, in particular, containing statements which throw light upon the scientific knowledge of this extraordinarily gifted blend of races. By far the more numerous allusions to these subjects occur in reference to the sons of Asclepius, Machaon and Podalirius, the former of whom Homer styles the faultless or excellent, *ἀμύμων*, physician. His value to the warriors must have been great, for we are told that his one life was worth a host, so useful was he for extracting the cruel bronze and mitigating pain (*Iliad* XI., 500 and sequel). According to the "Little *Iliad*," however, the Greeks finally lost his irreparable services, for he was, it will be remembered, killed by Eurypylus. The medical officers of the expedition to Asia were not non-combatants any more than the officers of our Army Medical Service are, whatever official view is held on the matter; they took their part in many fierce fights. On one occasion when their services were sorely needed Patroclus explains that Machaon just wounded in action was lying in a tent needing medical assistance himself; whilst Podalirius was engaged in the plain fighting the Trojans. There were, however, other surgeons among the Hellenes than the semi-divine sons of Asclepius, for Idomeneus fetches another medical man to

attend a comrade wounded in the thigh (XIII., 833-36); and at the commencement of Book XVI, it is explained that many of the more famous warriors lying wounded on the ships are being attended by physicians, *ἱγτροὶ πολυφάρμαχοι*. These other practitioners doubtless fought, if necessary, as did the two sons of Asclepius, but were only ordinary warriors, whereas the demigods were heroes and chiefs with many followers, coming as they did to join in the campaign with a fleet of 30 galleys. Those familiar with the story will recall that Podalirius and Machaon had been pupils of Chelron the Centaur,¹ who had also given lessons to Achilles, so that the latter subsequently, during the siege of Troy, was able to render first aid to the wounded Eurypylus and "applied a pain-assuaging drug, bruised in his hands, and spread upon the wound, stanching the blood flow, and so the anguish healed." Achilles, indeed, appears to have made good use of his medical knowledge, for we have an elegant vase painting depicting him binding up the wounded arm of his comrade

Patroclus. Strangely, however, there is no allusion in our present Homer² of Patroclus receiving a wound that was bandaged by Achilles, and so the painting must refer to some statement by the rhapsodist poets relating to the Trojan war or to some part of Homer's epic now lost. It will be seen that the point of a dart has penetrated the buckler arm of Patroclus, probably with but little force, having first had to transfix the shield. The Duc de Laynes, in describing this tableau, says the manner in which Achilles applies the bandage to the arm of his friend indicates the hero's dexterity and that of his surgical contemporaries or of Chelron the Centaur, his tutor, for it is done on a similar method as to-day. Achilles has commenced the unwrapping from the centre of the strip of material and not from the end of a roll, as advised by Hippocrates in cases of loss of blood. It is curious that Homer makes no allusion to medical men among the Trojans but speaks of wounded Agenor having his injury dressed by Helenus. He, however, is rather inclined to represent the Trojans as being more barbaric than the Achæans and may purposely have omitted to mention their medical arrangements. Incidentally he tells us the gods had their doctors like mortals, Pæon, their chief "medicine man," being absent when sadly needed by Venus,

¹ Chelron may have been medical pupil of Pæon or even of Apollo, for Healed, in a fragment, tells us the latter "knew all the remedies."
² The Egyptian Homeric papyri give many additional lines in all the books of the *Iliad* to those in our manuscripts of Homer, as if the Alexandrian scholars, and Aristarchus in particular, had reduced the length of the *Iliad* by nearly a tenth.

a misfortune he doubtless deeply regretted. The beautiful patient was, however, healed by her mother Dione, her hand having been pierced by the spear of Diomedes.

WHAT IS WHISKY?

WE understand that the settlement of this question is promised by a conference of all the parties concerned. At the County of London Sessions on Jan. 4th the appeal case was mentioned and the appellants, through their counsel, asked that the hearing of the appeal should be postponed until next April. The bench decided to suspend the appeals which will accordingly come up for consideration in the Sessions House, Clerkenwell, on April 12th. It appears that negotiations have been proceeding between the representatives of the Islington borough council and a committee of the patent spirit distillers of the United Kingdom. Whatever may be the agreement arrived at, any proposals to standardise whisky or, we presume, any other potable spirit must receive the sanction of Parliament. It is suggested that a committee should be appointed by the Local Government Board to decide upon this question of a standard. In that case, and if a satisfactory conclusion be forthcoming, the appeal will probably be withdrawn.

DECEMBER AT HOME AND ABROAD.

	Highest temperature.	Lowest temperature.	Mean daily maximum.	Mean daily minimum.	Mean temperature for month.	Range of temperature.	*Days with rain.	Total fall in month.

Lisbon	64	26	56	45	50.9	10	2	1.06

* Days with at least 0.04 inch.

The above table gives the chief meteorological elements at many places at home and abroad for last month. Compared with the corresponding figures for November the temperature shows a very general and substantial decrease of warmth. London in November had a mean temperature of 47.0° F., against 37.7° during December, and nearly every other place except Scilly, Torquay, and Lisbon experienced a similar reduction. As a whole, however, the Continent lost considerably more heat than this country; Berlin was 15° colder than it was during November, Paris 11°, and Florence 10°. Perhaps the most striking feature in the temperature statistics for December was the relatively small range between the warmth of the day and night. As is almost invariably the case the isolated Scilly Isles had the least range—the remarkably small difference of 6°—but next in order comes Berlin, where the mean nocturnal

temperature of 26° was only 7° lower than the mean temperature of the afternoon. Generally the month was more equable with us than abroad, but everywhere the diurnal range was rather less than usual. Scilly, which, with some of the most southern resorts abroad, successfully resisted the frost, had a greater mean daily warmth than Biarritz, Nice, and Florence, while the nights were milder than those at Rome and only slightly cooler than those at Naples and Palermo. Jersey and Torquay were also milder than Florence and the former milder than Nice, while the Devonshire resort had a mean temperature only about half a degree below that at Nice. Among the home resorts it is somewhat surprising to note the great difference in warmth between Torquay and Bournemouth, as well as the close resemblance between the figures of London and Birmingham. The warmest, and also one of the most equable of the foreign places, was Malta, where the temperature approximated very closely to that of the Channel Islands during an ordinary May. Abroad the weather was more rainy than during November except at Nice and Lisbon, but only at Biarritz and Algiers was the rain frequent as well as heavy. Nice had less rain than most places on the Riviera and also much sunshine, but the finest place of all the stations was probably Lisbon, where, except on two or three days, the month was remarkable for its fine, bright weather. Along the south coast of England the sunshine averaged rather more than two hours per day.

THE EMPIRICAL ORIGIN OF DRUGS.

IN the *Progrès Médical* of Oct. 20th, 1906, Dr. J. Noir deals in an interesting manner with the origin of drugs. He points out that modern medicine owes much to the empiricism, the folklore, the superstition, and even to the prejudices of past ages. It is obvious that in early times it was impossible for the physicians of the day to try all known plants for all known diseases. Some basis of selection being required, it occurred to these early physicians, deeply imbued as they were with religious and mystical ideas, that the Creator had not only endowed men with maladies but had also put within their reach appropriate remedies. They thought, indeed, that the Creator had indicated which remedies were to be used in special cases by causing plants to bear physical resemblances to the maladies for the cure of which they were intended. This theory dates back to a remote antiquity and it was generally entertained during the Middle Ages. Though fantastic, and now discredited, it served, however, a useful purpose, since it brought to light many remedies that otherwise would probably never have been known. Dr. Noir mentions several interesting examples of the empirical origin of drugs. The colour and shape of the chestnut (*le marron d'Inde*) were once considered to indicate its usefulness in the treatment of hemorrhoids. The narcotic properties of opium are considered first to have been known through the recognition of a faint resemblance between a poppy capsule and a human head. The little centaury possesses undoubted febrifuge properties but these might never have been discovered had it not been for the early empiricists who recognised in the four angles of the stem a sure indication of the proper sphere of usefulness of the plant in quartan fever. Indeed, they went so far as to reserve the triangular stems of centaury for the treatment of tertian fever. The demulcent properties of the lichens were first discovered through the obvious resemblance of certain lichens to the ramifications of the bronchi. Polygonum, the astringent properties of which are still sometimes employed in the treatment of dysentery, obtained a place in the ancient materia medica simply because the folds of the root resemble the loops of the intestines, thus clearly indicating its natural use. It is not surprising that so empirical a basis of selection should

have led to erroneous results. For example, the mandrake (*mandragora*) held high place in mediæval medicine owing to a resemblance between the roots and the human body. But, rightly or wrongly, mandrake is no longer used in medicine. There is, no doubt, some credit due to the early empiricists but it is probable that the properties of many remedies were originally discovered by accident. However, modern medicine owes much to ancient superstition and empiricism; indeed, it may be said that *empiricism* is still a potent force in medicine and it is doubtful whether it ever will be entirely eliminated from the therapeutic art.

RECOVERY FROM CEREBRO-SPINAL MENINGITIS UNDER INJECTIONS OF COLLARGOL INTO THE SPINAL CANAL.

COLLARGOL is a colloid, allotropic, soluble form of silver which was introduced by Credé in 1897 as an internal antiseptic. It may be administered by inunction, by the mouth, or by intravenous injection. Brilliant results have been reported from its use in infective disease by Professor Netter and others. At a meeting of the Société Médicale des Hôpitaux de Paris held on Oct. 19th, 1906, M. F. Vidal and M. Louis Raymond reported a case of cerebro-spinal meningitis in which a remarkable effect had been obtained from injecting collargol into the spinal canal. A woman, aged 31 years, was admitted into hospital on Nov. 14th, 1905, suffering from continuous headache with exacerbations which were provoked by the slightest sound or exposure to light. The neck was rigid and there were backache and Kernig's sign. The knee-jerks were exaggerated. The meningeal streak was easily obtained. The left pupil was more dilated than the right. The temperature was $102^{\circ}2^{\circ}\text{F}$. Lumbar puncture yielded turbid fluid containing cells, principally polynuclear, and meningococci. Other symptoms—retention and incontinence of urine and mental obtundation—developed. On the 21st the temperature was 104° , the pulse (which previously had been 120) rose to 144, and a fatal result seemed imminent. Lumbar puncture yielded fluid which was scarcely clouded. Five cubic centimetres of a 1 per cent. solution of collargol were injected into the sub-arachnoid space. Some hours later improvement was evident; the patient could understand questions, although she did not answer them. On the following day she could answer and the temperature had fallen to $100^{\circ}7^{\circ}$ and the pulse to 112. Recovery was interrupted by an attack of pneumonia but eventually was completed. During the whole of the disease polynuclear cells predominated in the cerebro-spinal fluid. This has been shown by Vidal, Sicard, and Ravaut to be the rule in acute non-tuberculous meningitis. During convalescence lymphocytes become predominant. In this case the total number of leucocytes in the cerebro-spinal fluid fell from 10,000 per cubic millimetre on admission to 671 when the symptoms were at their worst and the number of meningococci visible in the fluid was greatest. Four days after the injection of collargol the number of leucocytes rose to a height never before attained—14,000 per cubic millimetre. Most of the meningococci then seen were intracellular and there were also in the cells chocolate-coloured masses of collargol of varying size. Two days later only a few meningococci could be seen and these were dead, for they yielded no cultures on gelose. Netter has reported several cases of cure of cerebro-spinal meningitis by inunction or injection of collargol. Barth, Mauban, Papillon, and Esbach have published cases of recovery following intraspinal injection. Recovery from cerebro-spinal meningitis may take place spontaneously. But in the case reported above the rapid improvement and the remarkable changes in the cerebro-spinal fluid showed the beneficial action of the injection. At the same meeting Professor Dopfer reported

the case of a young soldier who had suffered for 20 days from cerebro-spinal meningitis which did not yield to ordinary treatment. 0.05 of a gramme of collargol was injected into the spinal canal. On the following day the temperature had fallen from 106° to $103^{\circ}2^{\circ}$, and the mental condition was improved. Recovery was then uninterrupted.

THE COLD MEAL.

THE solubility of most substances is increased by warmth and that fact alone suggests that the cold meal must be less digestible than the meal which consists of warm food. It is conceivable also that for the purposes of easy digestion the nearer the constituents of food are to a liquid state the more easily assimilable they must be. Certain fats are solid and hard at ordinary temperatures—as, for example, mutton fat or suet—while others, such as butter, are liquid at the body temperature, and the state of liquid being more readily amenable to digestive processes than the state of solid it follows that butter is more easily absorbed than suet. As a matter of fact, it is so physiologically. Frequently in chemical reactions, though the substances concerned refuse to act in the cold, yet on the slightest warming a mutual action takes place and soon is complete. Apart from these considerations warm food stimulates the flow of the digestive juices and thus prepares a condition decidedly in favour of its dissolution. As if to compensate for the uninviting and possibly, at the outset, depressing aspect of a cold meal it has been observed that the person to whom for some special, and it may be unfortunate, circumstances a warm meal is the exception commonly exhibits a desire to indulge in alcoholic stimulants. So far, therefore, the argument is opposed to the cold meal. On the other hand, very hot food may give rise to mischief, chiefly because during the meal there are almost certain to be considerable alternations of temperature which are calculated to excite a condition favourable to the production of local injury to the stomach. In point of fact, nothing which is very much hotter or colder than the stomach need be allowed to pass into that organ. Even an ice can be suffered to melt in the mouth before it is swallowed, and physiological considerations teach that such would be a wise course to adopt. The lower animals, as a rule, refuse hot food and when their food is animal prey the temperature of it is within a degree or two of that of their own bodies and, curiously enough, the ideal temperature of the food for man would appear to be that which is neither higher nor lower than his own body. Somewhere between 45° and 130°F . may be regarded as the limits of safety for food, and for drink the discreet range would be 50° as the minimum and 90° as the maximum.

SLUM DWELLINGS AND THEIR SUBSTITUTES.

THE accidental burning to death of a child, aged three years, whose clothing had been set on fire in a house in Grotto-place, Southwark, afforded recently an occasion to Dr. F. J. Waldo, coroner for the City and for Southwark, to call public attention to a dangerous and insanitary area in which he has for some time taken an interest. As medical officer of health of Southwark Dr. Waldo was able to call attention some years ago to three areas, known as Webber-row, King's Bench Walk, and Grotto-place, as insanitary areas which should be dealt with as such, and the London County Council's committee recommended that two of them should be included in a rebuilding scheme but was of opinion that Grotto-place did not urgently require reform. Dr. Waldo's observations at the late inquest, as reported in the *Globe*, show what Grotto-place is like. From there we gather that the houses have two rooms only, the lower one being below the level of the street. Each room

has one window only in front and none at the back, and the inhabitants of opposite houses can shake hands with one another from their upper windows across the intervening foot-way. The coroner called them cupboards, in which the circulation of fresh air was impossible, and it is to be hoped that the attention drawn to them by him may accelerate their much-needed demolition. Curiously enough another inquest held a few days later by the same coroner was on a child overlain by her mother in Webber-street, above mentioned. This occurred in model dwellings erected by the London County Council in substitution for the old ones, and it was elicited that the rents were as follows: one room, 5s.; two rooms, 6s. 11d. The former price certainly seems unduly high compared with the fluctuating and uncertain incomes of the working classes, and high rents are naturally conducive to overcrowding.

THE SURGICAL TREATMENT OF STERILITY IN THE MALE.

At a meeting of the American Association of Genito-Urinary Surgeons held at New York last year Dr. Edward Martin of Philadelphia brought forward a new and simple operation for sterility in the male, which is published in the *Boston Medical and Surgical Journal* of Dec. 6th, 1906. Sterility is an occasional result of gonorrhoea when it is due to occlusion of the vas deferens on both sides from double epididymitis. It is supposed that the occlusion occurs in the tail of the epididymis, where induration often may be felt. Adopting this view, Dr. Martin, in conjunction with Dr. Carnet, Dr. Levi, and Dr. Pennington, performed experiments on dogs to ascertain whether it was possible to short-circuit the vas deferens and the head of the epididymis and to provide a new route for the spermatozoa. The vasa on both sides were cut and ligatured a short distance from their origin in the epididymis and the proximal end was split and sutured into an opening made in the head of the organ. Subsequent ejaculations contained a normal number of motile and seemingly healthy spermatozoa. There appeared little tendency towards closure by cicatrization of the communication between the vas and the epididymis. The question remained, however, whether the spermatozoa thus short-circuited were fertile, since these bodies normally undergo some development in their passage through the epididymis. In the first case, in which the operation was performed in man, there was the usual history of repeated gonorrhoea, double epididymitis, a childless marriage, a wife treated by gynaecologists, and, finally, the discovery of azoospermia. The operation was performed on the left side; 14 days later the semen showed active motile spermatozoa, although not as many as normal. Marital relations were resumed 11 days after the operation and 281 days later the patient's wife was delivered of a child who strikingly resembled him. The spermatozoa again disappeared but returned after a long course of prostatic massage. The operation was performed in five other cases. One patient was lost sight of and conception did not follow in the other four cases, but in each there were other reasons for this result. The technique of the operation is very simple. Dr. Martin has operated under local anaesthesia without giving pain but he prefers to use ether. An incision one and a half inches long is made over the head of the epididymis in the back of the scrotum. The vas is freed from the cord. The epididymis is exposed and a small fragment of it is snipped out. A slit one-third of an inch long is made in the vas. This is best done with a sharp-pointed tenotome and a probe-pointed knife, similar to that used in incisions into the lacrymal duct. Four sutures, of silk or fine wire, are then passed with needles slightly curved, like those used by ophthalmic surgeons.

The needle is passed from the outer to the inner surface of the epididymis, and thence from the inner through the outer surface of the vas, one stitch being placed at either end of the incision and one at each side. The sutures are not tied until they are all passed. The tunica vaginalis is closed by buried catgut sutures and the wound in the skin by a continuous suture of either silk or catgut. The testicle is swathed in sterile cotton and immobilised by strapping. The patients were allowed to get up on the following day and to resume sexual relations within a week.

INEBRIATE REFORMATORIES AND DISEASE.

THE case of a woman named Rippin, charged before Mr. Fordham with being "drunk and incapable," brought out curious and undesirable conditions attaching to confinement in the institution for the care of inebriates carried on by the London County Council at Farmfield. The defendant had been sent to the Farmfield Inebriate Reformatory for a period of three years but had been let out on licence after two years because she was suffering from Bright's disease and because it was contrary to the regulations of the Farmfield Reformatory that persons suffering from disease requiring constant medical attention should be kept there. Owing to the comments made by Mr. Fordham when the case first came before him a gentleman from the solicitor's department of the London County Council attended at the adjourned hearing and stated that steps would now be taken to place the woman in the Eastern Counties Home and also that the County Council had modified views previously held by it as to the desirability of letting out inmates of such homes on licence. Mr. Fordham is to be congratulated upon having called public attention to a matter of some importance. The cure of inebriates is frequently a process the ultimate success of which is doubtful, and satisfactory results are likely to be rendered impossible and good work to be thrown away if the period of confinement is arbitrarily curtailed; at the same time, the inebriate whose persistence in the drink habit has rendered him liable to such detention is not unlikely to be found subject to disease requiring medical attention. That such a person needs to be kept in an inebriate home no less than his healthier fellow-drunkard hardly seems to be a matter for argument.

THE CULTIVATION OF MEDICINAL OPIUM IN INDIA.

A CORRESPONDENT to the *Times* has recently pointed out that although enormous quantities of opium are produced in India we are almost entirely dependent on Turkey for supplies of medicinal opium. The Indian drug contains only from 4 to 8 per cent. of morphine—a percentage too low for the economical manufacture of morphine, codeine, and other preparations of opium. The manufacturer prefers the Turkish variety, containing from 12 to 18 per cent. of morphine. Owing to measures which are being taken throughout the world to repress the opium habit¹ the area under poppy cultivation in India will dwindle year by year, and the suggestion is made that a part of the land should be devoted to the cultivation of opium sufficiently rich in morphine to be employed in medicine. It has already been experimentally shown that opium prepared from poppies grown in the hilly districts of the Himalayas yields 50 per cent. more morphine than that obtained from plants grown in the plains.² It rests with the Government of India to initiate experiments to determine whether it is not possible to produce on the commercial scale an opium containing as much morphine as the Turkish variety. It is very probable that something may be done in

¹ See THE LANCET, Oct. 13th, 1906, p. 1010.

² *Pharmaceutical Journal*, Sept. 22nd, 1906, p. 337.

this direction because no less than 587,000 acres were under poppy cultivation in India in 1904-05, and considerable reductions will be effected in the area under cultivation during the next few years. The growers are licensed by, and sell the products to the Government and unless the difficulty is met with energy great hardships will be inflicted upon the cultivators. India has passed through many similar agricultural troubles. When the demand for quinine reached large dimensions the Dutch ascertained by experiment which of the many species of cinchona gave the highest yield of the alkaloid and planted that species in Java on a large scale with very great success. About the same time over 1,000,000 cinchona trees were planted by the Government in India, but unfortunately the species chosen gave a poor yield of quinine, with a result that the trees had to be replaced. Thus the Dutch maintained the first position as producers of quinine to the detriment of India. Then, again, it is well known that the commercial production of artificial indigo has crippled another huge industry in India which was formerly the centre of the cultivation of indigo. The Government of India and its botanical advisers are now offered an excellent opportunity of atoning for the cinchona blunder, made in a former generation, by finding out methods of cultivating and producing opium as rich in morphine as the Turkish variety. India would then be able to share with Turkey the market for medicinal opium, the demand for which increases year by year.

THE PLAGUE FLEA AND ITS DESTRUCTION.

It has been definitely ascertained that the flea from a plague-infected rat contains the bacillus pestis in its stomach and that if a susceptible animal such as a rat, guinea-pig, monkey, or rabbit be placed in a room with infected fleas, the animals just mentioned will contract plague. The bacillus pestis will also be found in the faeces of the fleas and this excrement when rubbed into a susceptible animal's skin will prove fatal to that animal. The flea, therefore, either by direct inoculation, by bite, or by the faeces gaining access to the body by abrasion of the skin, conveys plague from animal to animal and place to place and from animal to man. Such is the substance of the observations made by Dr. John A. Turner, executive health officer of the Bombay municipality, in a paper read before the Bombay Medical and Physical Society in September, 1906. In some experiments which he was instrumental in having made the indications were clearly that the rat and the flea are disseminators of plague and therefore they must be exterminated. The flea persists in a room after the use of perchloride of mercury and even after sulphur fumigation. "Pesterine," a crude form of petroleum, was tried with the result that its application was found to render the room free from fleas. The plan which was adopted was to sprinkle the "pesterine" on the floor of the room to be disinfected and to spread it by means of a brush over the ceiling and the upper parts of the walls not omitting the lower parts; carefully going over all nooks, cracks, and ledges. A quantity is further poured down any rat hole seen in the floor. After 24 hours the room so treated is regarded to be fit for re-occupation. Pesterine appears also to be useful for disinfecting latrines and for killing flies, mosquitoes, and other insects and their eggs and larvae. It seems also to arrest putrefaction and its application checks the production of offensive smells. As an instance of its efficacy in destroying plague-contaminated fleas the following example, amongst many others, is given. A case of plague occurred in the room of a certain house on June 5th, 1906, the patient being removed to hospital two days afterwards. Guinea-pigs were kept in the room on the day of the outbreak and before disinfection. One of them was examined on the next day and was found to be full

of fleas. The place was disinfected, with pesterine in the manner described and the same two guinea-pigs infected with fleas were put in the room after disinfection. As a control two flea-free guinea-pigs were put in the room after disinfection and all four guinea-pigs were examined on the next day with the result that no flea was found. Finally, the guinea-pigs put in the room before the application of pesterine afterwards died from plague, while the other two remained alive. There was no doubt of the existence of rat fleas in the room before disinfection.

THE MANUFACTURE OF LEAD PAINTS AND COLOURS.

IN THE LANCET of July 14th, 1906, p. 107, we referred to a draft of regulations which, at the instance of the Home Office, the Secretary of State had issued in regard to the manufacture of lead paints and colours. These regulations are intended to supersede the existing special rules made under Section 79 of the Factory and Workshops Act, 1901. Employers were invited to send in any objections which they felt called upon to make with respect to these draft regulations. After consideration of the objections which were subsequently sent in the Secretary of State has now decided to make certain amendments in order to meet the difficulties pointed out by persons concerned. These alterations, we understand, can be made without materially affecting the utility of the regulations which will now be accepted by manufacturers without further objection. The provisions of the Act, however, require that the draft shall be republished as amended and in accordance with this requirement the Secretary of State has issued a formal notice intimating that further objections must be sent in by Jan. 17th, 1907.

THE STANDARDISATION OF DISINFECTANTS.

IN his annual report recently presented to the Minister of Agriculture Mr. H. Watkins-Pitchford, the Government bacteriologist and analyst of the laboratory at Pietermaritzburg, gives an interesting summary of his experience with the methods of determining the efficiency of disinfectant preparations. He concludes that while no entirely satisfactory system of standardising disinfectants exists at present the method devised by Dr. S. Rideal and Mr. J. T. Ainslie Walke appears to point the way to this desired end. The results he says, obtained by different workers and even by the same worker employing this method frequently vary within allowable limits. These variations he attributes to the following causes: (a) Unnoticed and trivial variations in technique; (b) differences in the resisting power of various strains of the same organisms and differences in physical characters of the growths of different organisms; (c) probable variation in the germicidal value of different samples of the same disinfectant; (d) too short a period for the final incubation; (e) too great intervals between the strength of dilutions; (f) the agents and durations of exposure of the organism to the action; (g) the necessity for introducing supposititious symbols when the two tables do not exactly coincide; (h) the acceptance as final of the results of only one series of observations; (i) other causes not yet determined; and lastly (j) the absence of a complete code of conditions rigid in every particular. The various disinfectants, he finds, possess specific powers over, or "germicidal affinities" for, particular micro-organisms. Discrepancies in the results obtained by this method would, he thinks, largely disappear if the carbolic co-efficient were taken to be the mean of several co-efficients obtained under standard conditions. Lastly, he suggests that the relative strength of a simple disinfectant might with advantage be expressed in terms

THE LANCET RELIEF FUND.

*For Members of the Medical Profession and their Widows
and Orphans when in Distress.*

—:—

ALMONERS.

THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE PRESIDENT OF THE GENERAL MEDICAL COUNCIL.

THOMAS WAKLEY, F.R.C.S. Eng.

THOMAS WAKLEY, Jun., L.R.C.P. Lond.

HON. AUDITOR.

SIR HENRY PITMAN, M.D. Camb., F.R.C.P.

—:—

THIS FUND will be provided year by year in the month of January to the amount of at least £300 solely by the Proprietors of THE LANCET, and administered free of cost, for the purpose of affording immediate pecuniary assistance to Medical Men, or their Widows and Orphans, in cases of *Acute Distress and Emergency*, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

Applicants must satisfy the Almoners of the Fund that they are qualified under the following regulation:—

* "The recipients shall be such persons as satisfy the Almoners that they possess one or other of the following qualifications—that is to say: (a) That the applicant holds a registered medical qualification, and that he has fallen into pressing need of immediate pecuniary relief; or (b) That they are persons who have been, previously to the date of application, legitimately dependent upon some person holding a registered medical qualification, and that they have pressing need of immediate pecuniary relief."

(In the case of Widows and Orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.)

To ensure the utmost despatch, the "Application Form" upon the other side should be filled up and forwarded (in an envelope superscribed "THE LANCET Relief Fund"), to the Secretary, Mr. CHARLES GOOD, THE LANCET Offices, Strand, London, W.C.

The application must be accompanied by two separate Testimonials (originals, not copies)—one from the Clergyman of the Parish or other resident Minister of religion, and one from a registered Medical Practitioner. Each Testimonial must state—(1) that the application addressed to the Almoners has been read; (2) how long the writer has known the applicant; (3) that the writer believes the statements made by the applicant to be perfectly truthful, and such as may be acted upon without further inquiry; and (4) may state any other particulars that the writer desires to place before the Almoners.

Testimonials written for the Almoners of the Fund will in no case be returned.

Private and Confidential.

APPLICATION FORM.

To the Almoners of The Lancet Relief Fund.

The applicant should here state shortly :—

1. The nature of the emergency that has arisen.

(In the case of Widows and Orphans the full names and date of death of the Husband or Father must be given.)

2. The circumstances out of which it has arisen.

The amount of the grant desired, and whether by way of loan (free of interest) or of gift.

4. If by way of loan, state when the loan will be repaid; and from what source the funds to repay it

expected to be forthcoming.

5. Whether the applicant is entitled or able in the circumstances which have arisen to look to any other source of assistance; and if so, what is the expected nature and extent of such assistance.

6. Whether the applicant is receiving, or has received during the past six months, pecuniary aid from any Medical Charity.

7. State how the applicant is qualified to receive assistance; vide regulation * on first page.

8. Particulars of:

Applicant's age _____

Number in family _____

How many are self-supporting _____

How many are partially dependent _____

How many wholly dependent _____

Applicant's Signature _____

Address _____

Date _____

No. _____

THE LANCET RELIEF FUND

of its value for the typhoid bacillus alone, the determination of its germicidal powers for organisms other than the typhoid bacillus being made the subject of a separate inquiry. Although for practical purposes it might suffice to state the relative value of any agent with respect to the typhoid bacillus alone, yet the ideal estimate of its utility as a general disinfectant would be secured, he thinks, by obtaining the mean of its several true carbolic co-efficients for all the organisms which can be cultivated in liquid media and with which the agent is required to deal.

THE Department of Public Health of Queensland in a bulletin dated Nov. 24th, 1906, reports that after an interval of 151 clear days bubonic plague has again made its appearance in Brisbane. 1 case was reported on Nov. 16th and 1 on the 23rd. Both patients were males, both died, and in both the diagnosis was confirmed by bacteriological examination. A bulletin dated Dec. 1st states that no further cases or suspicious cases occurred during the week ended on that date.

Professor Sir Robert William Boyce, Professor Ronald Ross, C.B., and Dr. John Lancelot Todd have been given his Majesty's Royal licence and authority respectively to accept and wear the Cross of Commander of the Order of Leopold II., which decoration has been conferred upon them by the King of the Belgians, Sovereign of the Independent State of the Congo, in recognition of their valuable services to the cause of medical science.

Mr. R. Henslowe Wellington, L.R.C.P. Lond., M.R.C.S. Eng., barrister-at-law, deputy coroner for Westminster lecturer on medical jurisprudence at the Westminster Hospital Medical School, and secretary of the Medico-Legal Society, has been elected a Corresponding Member of the Société de Médecine Légale de France, Paris.

THE usual clinical lectures and demonstrations at the Hospital for Sick Children, Great Ormond-street, on Thursday afternoons at 4 P.M., for the session January to March, will commence on Jan. 17th, when Dr. A. F. Voelcker will lecture on Peri- and Endo-carditis.

SALFORD SEWAGE DISPOSAL.—Salford has long been struggling with the difficulties of sewage disposal. A scheme by which it is hoped that these difficulties will be overcome is now approaching completion. Two bays of aerating filters about 3466 square yards in extent, which were begun last year, have been completed. These, with two others of the same area, are now working satisfactorily and two more bays are being proceeded with. Up to the present the outlay on the sewage works reconstruction scheme has been £124,535.

KALYRA SANATORIUM.—Kalyra Sanatorium for tuberculous patients is in South Australia, near Adelaide. In his report on the work of the institution for the 12 months ended June 30th, 1906, Dr. C. H. Reissmann states that during that period 117 patients were admitted, 32 were discharged "arrested," 44 were discharged "improved," 40 were discharged "unimproved," and four died. By "arrest" he means absence of all evidence of disease other than fibroid transformation or scarring. There must be no evidence of active disease either in the chest or elsewhere and no rales, rhonchi, or other adventitious sounds must be audible. There must be neither cough nor expectoration and no tubercle bacilli discoverable. The pulse, temperature, and respiration must be normal before and 20 minutes after returning from hill-climbing exercise. Dr. Reissmann considers that results based on tests less rigorous are misleading and tend to bring sanatorium treatment into disrepute, for readmissions will be numerous. He gives no details of treatment but promises to deal with this part of the subject in the *Australasian Medical Gazette*.

BRITISH MEDICAL BENEVOLENT FUND.

At the December meeting of the committee 25 applications were considered and sums amounting to £185 voted in relief to 19 of the cases. Two applications were passed over and four were postponed for further inquiry. An abstract of the cases assisted is appended:—

Daughter, aged 25 years, of late M.B. Lond., who practised in the West End. Just self-supporting, but recently had to borrow £10 to pay her mother's funeral expenses. Recommended by Dr. G. Fielding Blandford. Voted £5 in one sum.

Daughter, aged 56 years, of late F.R.C.S., L.S.A., who practised in Norfolk. Income £17 a year; has endeavoured to support herself for the last ten years by letting lodgings but has now broken down in health and has lost friends who could have helped. Recommended by Dr. R. L. Bowles and Dr. C. K. Boves. Voted £3 in 12 monthly instalments.

M.R.C.S., aged 52 years. Has practised for many years in Devonshire but is now obliged to give up on account of ill-health. Recommended by Dr. C. A. Hington. Voted £15 in 12 monthly instalments.

Son, aged 22 years (applying on behalf of younger members of the family), of M.R.C.S., L.R.C.P., who practised in Kent and in Lancashire but was killed a few months ago in a motor-car accident. The estate will only be able to pay about 5s. in the pound and a fund has been raised by the medical men of the towns in which the deceased practised to relieve the immediate need of the family and to send two of the boys out to Canada in the spring. Recommended by Dr. A. J. Allott. Voted £10 to be added to the fund mentioned.

Daughters, aged 53 and 51 years, of late L.F.P.S. Glasg., who practised in Scotland. Live rent free in house which belonged to their father and endeavour to exist by keeping a small shop. The elder sister has been an invalid for many years. The profits of the shop are very small and recently the applicants have been obliged to part with articles of furniture to avoid destitution. Recommended by Dr. William Frew. Voted £12 in 12 monthly instalments.

Daughter, aged 56 years, of late M.R.O.S., L.S.A., who practised in Bucks. Income insufficient for maintenance and is prevented earning a living by deafness and other infirmities. Recommended by Dr. E. Casey. Voted £5 in one sum.

Daughter, aged 45 years, of late M.R.C.S., L.S.A., who practised in London. Used to maintain herself as a secretary and companion but has had a long illness and is quite incapacitated. Is a candidate for the C.K.B.A. Recommended by Mr. Henry Stear, honorary local secretary. Voted £10 in two instalments.

Widow, aged 59 years, of L.R.C.P., L.R.C.S. Edin., who practised in London and Liverpool. Quite unprovided for at husband's death. Health now very bad. One son, aged 30 years, self-supporting but not able to help. Relieved eight times, £51. Recommended by Dr. C. E. Underhill. Voted £12 in 12 monthly instalments.

Daughter, aged 59 years, of late M.D. Edin. who practised in Herts. Has maintained herself until recently but is now obliged to nurse an invalid sister—an annuitant of this fund. Recommended by Dr. T. Orme Duffield. Voted £12 in 12 monthly instalments.

Widow, aged 63 years, of M.R.C.S., L.S.A., who practised in Essex. Only income a small pension; children unable to help; health indifferent. Relieved four times—£24. Recommended by Dr. J. E. Nevins, honorary local secretary. Voted £5 in one sum.

Daughter, aged 48 years, of late M.R.C.S., who practised in Yorkshire. Has nursed her mother for the last ten years and has now entirely broken down in health. No income. Relieved once, £12. Recommended by Mr. H. B. Maingay. Voted £12 in 12 monthly instalments.

Daughter, aged 62 years, of late L.S.A., who practised in Norfolk. Permanently incapacitated and only income £20 a year from the Royal Hospital for incurables. Relieved five times, £42. Recommended by Dr. S. J. Barton. Voted £5 in two instalments.

Widow, aged 59 years, of M.R.C.S., L.S.A., who practised in Leicester-shire. No income; lets lodgings and is at present in great and unavoidable distress. Five children, aged 18 to ten. Relieved six times, £22. Recommended by Dr. W. M. Renton. Voted £20 in 12 monthly instalments.

Widow, aged 66 years, of M.R.C.S., L.S.A., who practised in Staffordshire. Income only 25s a year; children unable to help. Is a candidate for Epsom College. Relieved three times, £32. Recommended by Mr. H. W. Kishmark. Voted £12 in 12 monthly instalments.

Daughter, aged 52 years, of late L.S.A., who practised in Staffordshire. Maintained herself as a governess for many years but is now incapacitated for any permanent work and dependent on a relative. Relieved five times, £56. Recommended by Dr. A. Boswell. Voted £5 in six instalments.

Widow, aged 61 years, of M.R.C.S. Eng., L.R.C.P. Edin., who practised in London. Income £24 a year from the rent of a house, but has been obliged to borrow to pay for necessary repairs. Relieved seven times, £72. Recommended by Dr. William Ewart. Voted £12 in 12 monthly instalments.

Daughter, aged 55 years, of late F.R.C.S., who practised in Cheshire. Maintains herself as a companion, &c., but at present has no engagement. Relieved once, £5. Recommended by Dr. W. Menden. Voted £5 in one sum.

Widow, aged 40 years, of L.S.A., who practised in Cheshire. Supports herself as a lady help but the salary is insufficient for the maintenance of her only child—a son, aged 11 years, who is a candidate for Epsom College. Relieved once, £12. Recommended by Mr. H. W. Kishmark. Voted £12 in 12 monthly instalments.

Widow, aged 64 years, of M.R.C.S., L.S.A., who practised in Staffordshire. Only income a pension of £20 a year. No children; health indifferent. Relieved eight times, £51. Recommended by Mr. H. Parsons Smith. Voted £5 in six instalments.

THE LANCET RELIEF FUND.

THIS Fund, which came into operation on the 1st of February, 1889, has for its Almoners the President of the Royal College of Physicians of London (Sir RICHARD DOUGLAS POWELL, Bart., K.O.V.O., M.D. Lond.), the President of the Royal College of Surgeons of England (Mr. HENRY MORRIS), the President of the General Medical Council (Dr. DONALD MACALISTER, M.A., LL.D., F.R.O.P. Lond.), Mr. THOMAS WAKLEY, F.R.O.S. Eng., and Mr. THOMAS WAKLEY, jun., L.R.O.P. Lond., with Sir HENRY PITMAN, M.D. Cantab., F.R.O.P. Lond., as Honorary Auditor.

FOR the guidance of those seeking assistance and of those desirous of recommending deserving cases, it may be useful to record that THE LANCET Relief Fund is sustained solely by the Proprietors of THE LANCET, who provide every January the sum of at least £300, which is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners, or to their widows and orphans, in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require. In the case of widows and orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.

WHEN the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established, and, as a result, the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. As the Almoners still receive applications for assistance for cases which are obviously of a *chronic* character, it is thought advisable to append a statement concerning cases of this nature which appeared in THE LANCET of Feb. 16th, 1889:—

"We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief"—

And who, it may be again pointed out, are likely to be benefited permanently thereby.

Eighteenth Annual Report of the Almoners,

For the year ending December 31, 1906.

In presenting their Eighteenth Annual Report the Almoners have to record that the balance in hand on Dec. 31st, 1905, was £232 13s. 1d., to which, on Jan. 1st, 1906, the Proprietors of THE LANCET added the sum of £300, making, with £1 repaid on loans, a total sum of £533 13s. 1d. available for grants during the year 1906.

The number of applications received by the Almoners during the year for assistance was 73, of which number 20 were rejected by the Secretary as quite outside the scope of the Fund; 8 were declined by the Almoners after due consideration; 2 applicants wrote acknowledging ineligibility after reading the regulations of the Fund; 10 Application Forms failed to be returned—doubtless owing to the applicants realising that their cases were not of a nature qualifying them to receive assistance from the Fund; 1 applicant had a self-propelling invalid chair, costing £6 7s. 9d., loaned for his use; and 32 applicants were relieved by gifts or loans of money ranging from £5 to £25. The relief of these 33 cases, a detailed list of which is given in the accompanying Statement of Accounts, involved the expenditure of the sum of £450 7s. 9d.—a sum considerably

above the normal income of the year, omitting balances brought forward and possible receipts from repayments of loans, and the largest sum voted in any one year, since the inauguration of the Fund in 1889. The total amount voted by the Almoners since the commencement of the Fund is £5643 6s. 3d.

The Almoners continue to receive expressions of gratitude for the assistance which they have afforded to applicants—in some urgent cases the relief was given on the day on which the application was received. As in past years, the timely help of the Fund has enabled more than one applicant to keep his practice together when pressing claims threatened to destroy his home and his means of livelihood and the widow and the orphan have also been helped at the moment of their greatest need.

The cases of "chronic" distress brought to the notice of the Almoners during the past year have not decreased in number; on the contrary, they have materially increased. Whilst sympathising with the applicants in their distress, the Almoners are quite unable to help them. The Fund at their disposal is not intended for such cases and would be

exhausted in the first month of the year were such claims to be met. The Almoners must again emphasise the fact that THE LANCET Relief Fund exists to meet cases of *sudden emergency*; and they will be especially obliged if gentlemen giving testimonials or recommending cases will bear this in mind.

Mr. Henry Morris having succeeded Mr. John Tweedy as President of the Royal College of Surgeons of England in July last, thereupon became an Almoner of the Fund, and kindly consented to act as such. The Almoners desire to record their warm appreciation of the valuable services rendered to the Fund by Sir John Tweedy during the period of his almonership, and to congratulate him upon the honour of Knighthood conferred upon him by His Majesty.

In conclusion, the Almoners would point out that they will at all times be glad to have their attention called to any cases of genuine distress coming within the scope of the Fund, but they trust that those recommending cases or giving testimonials will first take steps to satisfy themselves of the *bona fides*, as well as of the suitability, of such cases before endorsing them. In the administration of such a Fund as this the Almoners are of necessity largely guided in their decisions by the testimonials accompanying the applications

(Signed) R. DOUGLAS POWELL. HENRY MORRIS.

Balance at Bank, Dec. 31, 1906				...	73	5 4
£533 13 1						
£533 13 1						

I find by the Bankers' Book that the actual Balance on Jan. 1st, 1906, to the credit of the Fund was £232 13s. 1d., to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 1st, 1905.

The balance at the Bank on Dec. 31st, 1906, was the sum of £73 5s. 4d. I have also checked the receipts for disbursements and find the above account strictly accurate.

January 3rd, 1907

HENRY A. PITTMAN, Hon. Auditor.

THE WORKMEN'S COMPENSATION ACT, 1906.

THE Workmen's Compensation Act is here translated into ordinary language; its various parts are brought into consecutive order, references being given to the clauses, subsections, and pages, in order that medical men who have the leisure may refer to the printed Act without much trouble, and those who have not may be placed in possession of its details, so that they may be able to deal with their own affairs under the Act, or when asked by patients, as many of them will be, to give them information which will be of service. A correspondent with intimate knowledge of the Acts of 1897 and 1900 has added in brackets comments which we think may be of use, but we shall return to the consideration of the Act in an early issue of THE LANCET.

SHORT TITLE.

THE WORKMEN'S COMPENSATION ACT, 1906.

1. (1) (p. 1). A workman suffering personal injury by accident arising out of and in the course of his employment shall be compensated in accordance with the First Schedule of the Act.

First Schedule. 1. (1) (p. 18). If at death the workman leaves dependants on his earnings, his employer shall pay a sum equal to three years wages, or £160, whichever is the larger, but not exceeding in any case £300. If the workman has not been employed for three years by the employer, then the amount shall be calculated at 156 times his average weekly earnings while he has been employed.

(2) If the dependants are only partially dependent upon the earnings the amount is to be assessed by agreement or arbitration.

(3) If he leaves no dependants, reasonable expenses of medical attendance and burial not exceeding £10 shall be paid.

1. (1) (b). Where total or partial incapacity results from the injury a weekly payment not exceeding 60 per cent. of the average weekly earnings, not to exceed £1 per week, shall be paid.

1. (1) (b) (p. 19). If the workman is under 21 years of age and his weekly earnings under 20s. he is to receive 100 per cent., instead of 60 per cent., of his average weekly earnings, not, however, to exceed 10s. per week.

[This latter clause will make an immense difference to the rates of insurance for the cheaper kind of laundry, factory, and domestic labour.]

First Schedule. 2. (17) (p. 22). After a weekly payment has been continued for not less than six months the employer may redeem the further payments by payment of a lump sum based on the cost of an immediate life annuity purchased from the National Debt Commissioners, equal to 75 per cent. of the annual value of the weekly payments, but nothing in this section is to prevent mutual agreements to settle.

[An annuity of 75 per cent. of £58 a year in a person of the age of 25 would cost about £700; this will bring home to everyone the importance of being covered by insurance.]

Second Schedule. (9) (a), (b), (c), (d), (e). Very stringent rules are made requiring any settlement whether made by committee, arbitrator, or by agreement to be registered at the county court, and the registrar may refuse to register, or the judge may within six months remove a settlement from the register; if it is thought that the settlement was obtained by "fraud or undue influence or other improper means."

[This is most important as it will prevent the sharp and unreasonable settlements which have been made by lay inspectors and unqualified men, late medical students or unqualified assistants who have been freely employed by certain insurance offices.]

1. (2) (a) (p. 1). The employer shall not be liable in respect of an injury which does not disable for at least one week.

First Schedule. (a) (p. 18). If the incapacity lasts less than two weeks no compensation shall be payable in respect of the first week.

[These two clauses are giving great anxiety to employers and insurance managers, for it follows that in any disability lasting over a fortnight the workman will be able to claim compensation from the date of the accident and therefore there will be great temptation to magnify slight injuries. If medical men have this clearly before them they will be chary of giving medical certificates before the expiration of the first fortnight after the accident, especially as this will not in any way prejudice the workman, for, as will be seen later, a medical certificate is not required to be sent with the notice of accident.]

1. (2) (c) (p. 2). A workman cannot claim compensation for injury if it is attributable to his "serious and wilful misconduct," unless the injury results in death or serious and permanent disablement.

[The Act of 1897 made no exception for death or serious injury.]

(3) Any disputed matters are to be settled as provided in the Second Schedule, p. 24—namely, by a committee, an arbitrator, or, in absence of agreement as to these, by a county court judge.

Second Schedule. (5) (p. 24). A judge may, if he thinks fit, summon a medical referee to sit with him as assessor.

[This is an innovation, and if it is acted on will constitute an ideal method of dealing with disputed claims, as the judge will be able to give his decision, after hearing an unbiased medical opinion and after being able to ask any questions on the medical points that he may consider necessary.]

(4) If an action is brought against an employer independently of this Act and it falls the Court may assess the compensation due under this Act and deduct therefrom all or part of the cost caused by the bringing of the abortive action.

2. (1) (p. 2). Notice of the accident must be given "as soon as practicable" and before the workman has voluntarily left the employment

in which he was injured and within six months of the accident or date of death; (a) and (b) (p. 3), however, provide that any defect or inaccuracy in the notice shall not be a bar to the proceedings if the employer is not thereby prejudiced in his defence, or if a failure to make a claim was occasioned by mistake, absence from the United Kingdom, or other reasonable cause.

2. (2) (p. 3). Notice of accident shall give the name and address of the person injured and state in ordinary language the cause of the injury and date of the accident and must be served on the employer by delivering it at his address or by registered letter.

[The questions of schemes of insurance of workmen, subcontracting, and bankruptcy of employers on pages 3, 4, 5, 6, and 7, are omitted as ordinary medical men would not be interested.]

7. (1) (p. 7). All members of the crew of any British ship are brought under the Act, and it was stated in the House of Commons that this includes lascars and other foreign seamen employed.

8. (1) (p. 9). Where a certifying factory surgeon certifies that a workman is disabled from earning full wages, or is suspended from work or that his death has been caused by either of the following diseases he or his dependants shall be entitled to compensation as if the disease was a personal injury by accident, under, however, certain special regulations set forth on pages 9, 10, 11.

Third Schedule.—Section 8.

Disease.	Description of process.
Anthrax.	Handling of wool, hair, bristles, hides, and skins.
Lead poisoning or its sequelae.	Any process involving the use of lead or its preparations or compounds.
Mercury poisoning or its sequelae.	Any process involving the use of mercury or its preparations or compounds.
Phosphorus poisoning or its sequelae.	Any process involving the use of phosphorus or its preparations or compounds.
Arsenic poisoning or its sequelae.	Any process involving the use of arsenic or its preparations or compounds.
Ankylostomiasis.	Mining.

8. (6). The Secretary of State may make orders extending the provisions of this section to other diseases, or injuries due to the nature of the employment not being injuries by accident, with or without modification.

8. (f). An employer or workman aggrieved by the action of a certifying or other surgeon in giving or refusing a certificate of disablement or in suspending or refusing to suspend a workman for the purposes of the section, can, under the regulations of the Secretary of State, have the matter referred to a medical referee whose decision shall be final.

9. (1) (pp. 12 and 13). The Act is extended to all servants of the Crown, except the naval and military, and the head of any department is to be deemed the employer.

10. (1) (p. 13). Power to the Secretary of State to appoint legally qualified practitioners as medical referees, their remuneration to be paid out of moneys provided by Parliament.

The following clause being important to the profession is quoted in full: "Where a medical referee has been employed as a medical practitioner in connexion with any case by or on behalf of an employer or workman or by insurers interested, he shall not act as medical referee in that case."

First Schedule. 1. (4) (p. 20). Any workman after giving notice of accident must submit himself for examination by a duly qualified medical practitioner provided and paid by the employer, if required, but by

(15) (p. 21), he shall not be required to submit himself for examination under paragraph (4) or (14) otherwise than in accordance with the regulations of the Secretary of State, or at more frequent intervals than may be prescribed in these regulations. When a workman has submitted himself to examination by a medical practitioner paid by the employer or himself, and either has within six days sent a copy of the medical report to the other, and in the event of no agreement being come to as to the workman's condition "the registrar of a county court on the application of both parties may on payment by the applicants of such fee not exceeding £1 as may be prescribed, refer the matter to a medical referee." The medical referee's certificate is to be conclusive evidence as to the matters so certified. If the workman refuses to submit himself to the examination of a medical referee, his right to compensation will be suspended until such examination has taken place.

(16) Any weekly payment may be reviewed at the request of employer or workman, and increased or diminished in default of agreement by arbitration.

(18) Any workman ceasing to reside in the United Kingdom will not be entitled to any weekly payment unless a medical referee certifies that the incapacity resulting from an injury is likely to be of a permanent nature, in which case, however, he may have quarterly payments subject to proof of identity and continuance of the incapacity.

(19) No weekly payment or sum paid in redemption can be assigned, charged, or attached.

[It will be seen that the duties of the medical referees are very largely increased and that their decisions will be conclusive and final; the success of the Act will therefore depend, so far as regards the medical arrangements, on (1) whether the medical referees who are appointed have the confidence of the profession in their several districts; (2) on the support given to them by the county-court judges; and (3) on the regulations for medical examinations which are to be made by the Secretary of State.]

13. (p. 14). "Workman" does not include any person employed otherwise than by way of manual labour whose remuneration exceeds £250 a year, or a person whose employment is of a casual nature and who is employed otherwise than for the purposes of the employer's trade or business, or a member of a police force, or an outworker, or a trade or business, or a member of a family dwelling in his house but, save as aforesaid, means any person who has entered into or works under a contract of service or apprenticeship with an employer, whether by

way of manual labour, clerical work, or otherwise, and whether the contract is expressed or implied, is oral or in writing.

[The Act therefore includes ordinary workmen of all kinds regularly employed, clerks, secretaries, medical assistants and dispensers, curate, lay readers, and nurses, and last, but not least, all domestic servants.]

16. (1). The Act will come into operation on the first day of July, 1907, and will not apply to any case where the accident happened before that date, except so far as it relates to references to medical referees, and proceedings consequential thereon.

Looking Back.

FROM

THE LANCET, SATURDAY, Jan. 10th, 1829.

*On Dancing and on its advantages to young Persons, when it is scientifically taught.*¹

THOSE who affect to think that the most indifferent of our actions should always be described in a manner which indicates the highest degree of morality, speak of dancing in terms that I shall not repeat: religious fanatics speak of it in a way that is connected with their modes of thinking; the dealers in gymnastic exercises, as they are called, mention dancing in terms which show that they think it very inferior, in point of utility, as well as in the power of exciting pleasurable sensations, to their own exercises. Those who attend to these discourses, will be in a condition to judge how far those opinions are correct; but as I differ in opinion, upon this subject, from all those persons that have been mentioned, I shall only consider dancing as something that either has, or may have, peculiar effects upon the health, as well as upon the form of those who practise it. Dancing is one of the most healthy, as well as one of the most pleasing, amusements that has been, or that can be practised, by females of the superior classes of society; if it is learned from those who are well qualified to teach it, and practised, as it ought to be, consistently with the instructions by which it is taught, it will contribute more to improve the health, as well as the form, of those who practise it, than any other exercise. I advance this decisively, because I have lately seen a book, from which I have extracted the following passage:—

"I have adverted to the over anxiety to educate girls in the fascinating accomplishments of music, drawing, and dancing; in the prosecution of which, they are confined in hot rooms, and forced into strained attitudes for hours together; and to the manner in which it has led, in different ways, to the most distressing circumstances. If long perseverance, in any habit, be sufficient to produce distortion and deformity in the spinal arrangement of adult and athletic males, it will surely be much more likely to induce them in the sickly and pampered children of the affluent. Though various causes may be assigned for the increased prevalence of these complaints in our own time, I am convinced that the relaxing effects of hot rooms, and a too ardent pursuit of feminine accomplishments, are the principal ones. By admitting the elasticity of the fibrous structure, and its disposition to stretch under certain favourable circumstances, we are enabled to understand many obscure actions which are going on in the animal economy, and in particular, to fix the doctrine of spinal distortion upon a simple and lasting foundation."

It would be an unwarrantable display of false tenderness to the writer, to use any of the terms that are commonly employed to describe the writings of medical men, to give a character to this passage; it will, however, be doing him justice, to use a term that is well understood in a neighbouring country, when they say a thing is all botheration; or if he should prefer an English explanation, I would say, the whole is a tissue of vulgar impudence that has no foundation in truth, and has been used to confound those who only wish to know the plain meaning of plain words. This being the case, as I shall have occasion to pay much attention to the writings of this person, at a future period, I shall only endeavour, at present, to show what are the real effects of dancing, that those who are interested in understanding it, may see how little this person knows about the matter.

MEDICINE AND THE LAW.

The Food of the People.

AMONG recent cases in which the purity of food offered for sale has formed the subject of legal proceedings may be noted a seizure of unsound fruit in Battersea with regard to which Mr. De Grey held that the defendant, a wholesale dealer, was protected by a notice in his yard that "Packets of fruit are sold on the express condition that the buyers shall sort the said contents and before offering any part to the public destroy the unsound portion." It will be interesting to see if this rather ingenious notice is adopted as widely as its success in a particular instance would suggest that it may be and whether other magistrates will follow Mr. De Grey's example should a similar case come before them. It seems open to the objection that the vendor was imposing a condition which he would find extremely difficult, if not impossible, to enforce. In another case at Greenwich police-court a butter merchant, trading at Sydenham, who had been previously convicted, was fined £40 with 12s. 6d. costs, or in the alternative two months' imprisonment, for selling butter adulterated with 80 per cent. of foreign fat. At Enfield two defendants have been fined £10 each with the alternative of one month's imprisonment for selling beer not brewed by the firm whose labels were affixed to the jars. The defence was raised that the printed slips of paper which the prosecution said were labels to deceive the customer were the headings of invoices stuck on as pieces of paper only, in order that the defendant might write upon them, with the further suggestion that the ales of the eminent firm of brewers in question would thereby be advertised. At an inquest held in Battersea by Mr. Troutbeck the death of a woman who had died from eating fried fish was inquired into with no very definite result, the coroner dwelling upon the importance of the constant inspection of the people's food-supply. The fish in this instance had not been fried in oil but in dripping purchased from a restaurant, which increased the difficulty of tracing the source of whatever caused the death of the deceased, and the jury brought in a verdict of "Accidental death."

Confidence withheld from a Medical Man.

At a recent inquest at Battersea held before Mr. Troutbeck the evidence showed that the deceased, a married woman, died from a fatal dose of ammonia which she had taken by mistake for gin, and that her husband, who was aware of what she had done, called in a medical man; but apparently, through a desire to conceal his wife's drinking habits, did not tell him of it. Indeed, when Mr. Percy A. Palmer, who attended her, asked him whether she had taken poison he denied it and did not admit it until it was too late. As Mr. Troutbeck observed, medical men are sometimes expected to divine what their patients are suffering from as if they were magicians, and to cure them in spite of their, or their friends', denials of material facts and their refusal to volunteer information. To persist in the endeavour to elicit all necessary details would seem to be the only course open but this cannot always be done effectually when the symptoms are not marked enough to assist the cross-examination. Apparently no liquid has a sufficiently powerful and distinctive odour to prevent it from being mistaken for the spirits usually consumed by those who habitually drink to excess.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9714 births and 6379 deaths were registered during the week ending Jan. 5th. The annual rate of mortality in these towns, which had been equal to 19.1 and 19.7 per 1000 in the last two weeks of December, further rose to 22.4 in the week under notice. During the 13 weeks of last quarter the death-rate in these towns averaged 16.2 per 1000; the rate during the same period in London being 16.0. The lowest death-rates in the 76 towns during last week were 6.4 in Hornsey, 12.2 in East Ham, 13.1 in West Hartlepool, and 13.5 in Darrow-in-Furness; the rates in the other towns ranged upwards to 27.6 in Preston, 28.0 in Oldham, 32.4 in Sunderland, and 36.4 in Middlesbrough. The 5379 deaths in the 76 towns showed a further increase of 891 upon the numbers in recent

¹ Excerpt from "Lectures on Muscular Action, and on the Cure of Deformities." By Mr. Stedman.

weeks, due in great measure to delay of registration during Christmas week. They included 478 which were referred to the principal epidemic diseases, against 425 and 430 in the two preceding weeks; of these, 158 resulted from measles, 99 from diphtheria, 90 from whooping-cough, 54 from diarrhoea, 44 from scarlet fever, 33 from "fever" (principally enteric), and not one from small-pox. The deaths from these epidemic diseases were equal to an annual rate of 1.6 per 1000 in the 76 towns; the rate in London from the same diseases being 1.5. No death from any of these epidemic diseases was returned last week in Brighton, Hornsey, York, West Hartlepool, Ipswich, or in five other of the 76 towns; the annual death-rate therefrom, however, ranged upwards to 3.1 in Salford and Hull and 6.7 in Rotherham and Warrington. The fatality of measles showed the largest proportional excess in Rochdale, Wigan, Rotherham, and Warrington; diphtheria in Aston Manor, Rotherham, Reading, and Derby; and whooping-cough in Blackburn, Tottenham, Leyton, Hastings, and Middlesbrough. Scarlet fever caused 12 deaths in Manchester and Salford, and nine in Sheffield. Four deaths from "fever" were returned both in Bristol and in Birmingham. No case of small-pox has been under treatment in the Metropolitan Asylums Hospitals since the end of June last. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 3807 and 3846 in the two preceding weeks, declined to 3707 at the end of the week under notice; 309 new cases were admitted to these hospitals during the week, against 334 and 237 in the two previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had steadily increased in the five preceding weeks from 312 to 561, further rose to 718 in the week under notice, and exceeded the corrected average in the corresponding week of the last five years by 280; 87 deaths were also referred to influenza. The causes of 87, or 1.2 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 43 other of the 76 towns; the proportion of uncertified deaths, however, again showed a considerable proportional excess in Liverpool, Birmingham, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19.9 and 19.0 per 1000 in the two preceding weeks, rose again to 22.9 in the week ending Jan. 5th, and exceeded by 0.5 the mean rate during the same week in the 76 English towns. The rates in the eight Scotch towns ranged from 15.0 and 21.2 in Perth and Leith, to 29.0 in Dundee, and 31.8 in Paisley. The 796 deaths in the eight towns showed an increase of 144 upon the number returned in the previous week and included 71 which were referred to the principal epidemic diseases, against 69 and 55 in the two preceding weeks. These 71 deaths were equal to an annual rate of 2.0 per 1000, which exceeded by 0.4 the rate from the same diseases in the 76 English towns; they included 18 which were referred to whooping-cough, 16 to diarrhoea, 14 to "fever," 11 to diphtheria, ten to measles, two to scarlet fever, and not one to small-pox. The 18 fatal cases of whooping-cough corresponded with the number in the previous week, and included 11 in Glasgow and two both in Dundee and Aberdeen. Of the 16 deaths attributed to diarrhoea five occurred in Edinburgh and in Dundee, and three in Glasgow and in Paisley. The 14 deaths referred to "fever" showed a marked increase upon recent weekly numbers; no fewer than 13 were returned in Glasgow, of which seven were certified as cerebro-spinal meningitis. Diphtheria caused four deaths both in Glasgow and in Edinburgh; measles, six in Aberdeen and two in Glasgow and in Edinburgh; and the two fatal cases of scarlet fever were returned in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 119 and 167 in the two preceding weeks, further rose to 182 in the week under notice, and exceeded the number returned in the corresponding week of last year by 49. The causes of 46, or 5.8 per cent., of the deaths registered during the week were not certified or not stated; the mean proportion of uncertified deaths in the 76 English towns during the week did not exceed 1.2 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 28.8 and 18.4 per 1000 in the two preceding weeks, rose to 31.9 in the week ending Jan. 5th. During the 13 weeks of last quarter the death-rate in the city averaged 23.9 per 1000, the mean rate during the same period in being only 16.0 in London and 16.2 in Edinburgh. The 239 deaths of Dublin residents during the week under notice showed an increase of 110 upon the exceptionally low number returned during the Christmas week; they included 19 which were referred to the principal epidemic diseases, against nine and five in the two preceding weeks. These 19 deaths were equal to an annual rate of 2.5 per 1000, against 1.5 in London and 1.8 in Edinburgh. The 19 deaths from these epidemic diseases in Dublin last week included nine from diarrhoea, seven from whooping-cough, three from measles, and not one either from small-pox, scarlet fever, diphtheria, or "fever." The fatal cases of diarrhoea, whooping-cough, and measles showed a considerable increase upon recent weekly numbers. Nine inquest cases and seven deaths from violence were registered during the week; and 79, or 33.1 per cent., of the deaths occurred in public institutions. The causes of 16, or 6.7 per cent., of the deaths registered in the city during the week were not certified; the percentage of uncertified deaths in the week under notice did not exceed 0.1 in London, while it was 9.5 in Edinburgh.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1906.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 7.5 per 1000 of the population, estimated at 4,721,217 persons in the middle of last year. In the three preceding months the rates had been 9.0, 11.1, and 9.5 per 1000 respectively. The lowest rates last month were recorded in Kensington, Hammer-smith, City of Westminster, St. Pancras, Holborn, and the City of London; and the highest rates in Paddington, Fulham, Bermondsey, Battersea, Deptford, and Woolwich. The prevalence of scarlet fever showed a further decrease during December as compared with other recent months; among the various metropolitan boroughs this disease was proportionally most prevalent in Paddington, Fulham, Bermondsey, Battersea, and Woolwich. The Metropolitan Asylums hospitals contained 3787 scarlet fever patients at the end of last month, against 3360, 4111, and 4003 at the end of the three preceding months; the weekly admissions averaged 328, against 461, 543, and 430 in the three preceding months. Diphtheria was considerably less prevalent last month than it had been in the preceding month; this disease showed the greatest proportional prevalence in Fulham, Battersea, Wandsworth, Deptford, Greenwich, and Lewisham. The number of diphtheria patients under treatment in the Metropolitan Asylums hospitals, which had been 844, 1062, and 1076 at the end of the three preceding months, had declined again to 995 at the end of last month; the weekly admissions averaged 128, against 130, 175, and 153 in the three preceding months. The prevalence of enteric fever showed a marked decline last month; among the various boroughs this disease was proportionally most prevalent in St. Marylebone, St. Pancras, Finsbury, the City of London, and Camberwell. There were 134 enteric fever patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 139, 200, and 161 at the end of the three preceding months; the weekly admissions averaged 18, against 28, 34, and 24 in the three preceding months. The greatest proportional prevalence of erysipelas was recorded in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Bermondsey, and Deptford. The 22 cases of puerperal fever notified during the month included two each belonging to Paddington, Kensington, Fulham, St. Pancras, Lambeth, Battersea, and Camberwell.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending Dec. 29th the deaths of 6626 persons belonging to

* Including membranous group.

were registered, equal to an annual rate of 18·3 per 1000; in the three preceding months the rates had been 17·1, 13·6, and 14·7 per 1000 respectively. The death-rates last month ranged from 9·2 in Hampstead, 11·3 in Stoke Newington, 13·7 in Lewisham, 14·8 in Hammersmith, 15·1 in Wandsworth, and 15·5 in Chelsea, to 21·6 in Bethnal Green, 23·2 in the City of London, 23·8 in Shoreditch, 24·3 in Holborn, 25·1 in Bermondsey, and 25·4 in Finsbury. The 6626 deaths from all causes in London last month included 414 which were referred to the principal infectious diseases; of these, 100 resulted from measles, 44 from scarlet fever, 75 from diphtheria, 98 from whooping-cough, 30 from enteric fever, and 67 from diarrhoea. No death from any of these diseases was recorded in the City of London; among the metropolitan boroughs they caused the lowest death-rates in the City of Westminster, Hampstead, Stoke Newington, and Holborn; and the highest rates in Finsbury, Bethnal Green, Stepney, Bermondsey, Lewisham, and Woolwich. The 100 deaths from measles were 85 below the corrected average number in the corresponding periods of the four preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Bethnal Green, Stepney, Poplar, Bermondsey, Wandsworth, and Woolwich. The 44 fatal cases of scarlet fever were slightly in excess of the corrected average number; this disease showed the highest proportional mortality in Hammersmith, Paddington, Shoreditch, Bermondsey, Battersea, and Greenwich. The 75 deaths from diphtheria were also just above the average for the corresponding periods of the four preceding years; the highest death-rates from this disease were recorded in Paddington, Shoreditch, Bermondsey, Wandsworth, Deptford, Greenwich, and Lewisham. The 98 fatal cases of whooping-cough were 16 fewer than the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Islington, Finsbury, Bethnal Green, Southwark, Battersea, and Camberwell. The 30 deaths from enteric fever showed a considerable decline from the average number in the corresponding periods of the four preceding years; the greatest proportional mortality from this disease was recorded in Hammersmith, St. Pancras, Finsbury, Stepney, and Woolwich. The 67 fatal cases of diarrhoea were almost identical with the corrected average number; the highest death-rates from this disease were recorded in Paddington, Fulham, Chelsea, Shoreditch, and Poplar. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was more than 20 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 144 per 1000. The lowest rates of infant mortality were recorded in Hammersmith, St. Marylebone, Hampstead, Stoke Newington, Hackney, and Woolwich; and the highest rates in Chelsea, Islington, Finsbury, Shoreditch, Bethnal Green, and Bermondsey.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: W. M. Craig to the *President*, for three months' course at West London Hospital; and R. O. Munday to the *Aboukir*. Staff Surgeons: H. O. Arathoon to the *Diamond*; and W. G. Westcott to the *Essex*. Surgeons: G. M. Eastmont to the *Magnificent*; A. R. Thomas to the *Terrible*; H. L. Geoghegan to the *Victorious*; R. B. Scribner to the *Majestic*; W. P. Yetts to the *Leviathan*; G. E. Macleod to the *Glory*; J. R. Muir to the *Albion*; R. O. P. McDonagh to the *Cressy*; E. S. Wilkinson to the *Andromeda*; R. Kennedy to the *Spartiate*; S. Croneen to the *Cornwall*; W. L. Martin to the *Cumberland*; H. A. Browning to the *Donegal*; T. W. Jeffery to the *Aboukir*; G. O. O. Ross to the *Niobe*; P. F. Minett to the *Europa*; A. H. S. Richardson to the *Cambridge*; G. Taylor to the *Ariadne*; N. J. Roche to the *Hannibal*; and G. E. Duncan to Plymouth Hospital.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon John Walter Slaughter has been placed on the retired list of his rank, at his own request (dated Jan. 3rd, 1907).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel G. W. Brazier-Greagh, C.M.G., and Lieutenant-Colonel R. W. Wright have joined at Woolwich.

Captain G. J. S. Archer, from the Royal Army Medical College, has been appointed to Londonderry for duty.

ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned Surgeon-Captains to be Surgeon-Majors:—Alexander B. Lyon (dated Feb. 10th, 1906); James P. S. Ward (dated Nov. 21st, 1906); Robert T. Ferguson (dated Dec. 5th, 1906). Surgeon-Lieutenant Harry Stallard to be Surgeon-Captain (dated Dec. 27th, 1906).

DEATHS IN THE SERVICES.

Surgeon-Major-General Frederick William Wade, A.M.S. (retired), on Dec. 26th, 1906, aged 69 years. He entered the service as assistant surgeon in 1857, became surgeon in 1872, surgeon-major in 1873, deputy surgeon-general in 1883, surgeon-colonel in 1887, surgeon-major-general in 1892, and retired in 1894.

Surgeon-General Richard Chapman Lofthouse, A.M.S. (retired). He entered the service as assistant-surgeon in 1854, became surgeon in 1867, surgeon-major in 1873, brigade-surgeon in 1879, and retired in 1884 with the rank of deputy surgeon-general. He served with the Prince of Wales's 10th Royal Hussars in the Crimean war and was present at the siege and fall of Sevastopol (medal and clasp and the Turkish medal). He served in the Indian Mutiny with the 14th King's Light Dragoons under Sir Hugh Rose and Sir Robert Napier, took part in many important actions, was mentioned in despatches, and received the medal and clasp for Central India. He also served during the occupation of Egypt from 1882 to 1884.

THE PROMOTION EXAMINATIONS OF ARMY MEDICAL OFFICERS.

When the new Army Medical Advisory Board gets to work it might usefully turn its attention, among other things, to the subject of the examination of medical officers for promotion. It is questionable whether the tendency of the present day is not to a system of over-examination, as we are disposed to think is the case, but this is not the point with which we are now more immediately concerned. This is, rather, whether the subjects taken up should not, as applied to a scientific branch of the service, undergo some modification in order to give them a more direct and practical bearing upon a medical officer's special duties with the view of showing his efficiency in that respect. While we recognise that it is desirable that a medical officer for administrative and disciplinary purposes should in a general way be acquainted with such subjects as military law, the terms of the Geneva Convention, the laws and customs of war, and with the medical organisation and regulations of the armies of other countries, we nevertheless think that such knowledge must be regarded as relatively unimportant and subordinate to that directly bearing upon the special work and duties of a medical officer as such.

PROMOTION IN THE ARMY MEDICAL SERVICES.

That this has been the subject of a feeling of unrest and dissatisfaction of late in the Army Medical Services is much to be regretted, but the existence of this state of affairs cannot, we think, be denied. Whether rightly or wrongly we cannot say, but by some this was ascribed to the influence of the Advisory Board. We regard it, however, as a move in the right direction that all selections for promotion of officers to ranks having a fixed establishment are primarily to be made by a board consisting of the Director-General and the surgeons-general serving at home, who will make their reports and recommendations directly to the Selection Board at the War Office.

FOREIGN UNIVERSITY INTELLIGENCE.—Berne:

Dr. Kurt Kottmann has been recognised as *privat-docent* of Medicine.—*Bonn*: Dr. Robert Bonnet of Greifswald has been offered the post of Professor of Anatomy in succession to Dr. Freiherr v. la Valette St. George, who retires at the close of the winter session.—*Clausen*: Dr. Konrad has been recognised as *privat-docent* of General Pathology and Therapeutics.—*Freiburg*: Dr. Wilhelm Hildebrandt has been recognised as *privat-docent* of Medicine.—*Paris*: Dr. Raphaël Blanchard has been appointed Professor of Parasitology and of Medical Natural History.—*Vienne*: Dr. Max Richter has been appointed Extraordinary Professor of Forensic Medicine; Dr. Theodor Panzer, Extraordinary Professor of Medical Chemistry; Dr. Otto Loewi, Extraordinary Professor of Pharmacology; and Dr. Otto Ritter von Fürth, Extraordinary Professor of Medical Chemistry.—*Würzburg*: Dr. Brückner has been recognised as *privat-docent* of Ophthalmology.

"Audi alteram partem."

SCARLET FEVER MORTALITY AND HOSPITAL ISOLATION.

To the Editors of THE LANCET.

SIRS,—I fear the purport of my letter published in THE LANCET of Dec. 15th, 1906, p. 1685, has been misunderstood by yourselves and Dr. W. G. Willoughby. Perhaps I did not express myself with sufficient clearness. Your original article claimed that hospital isolation had had a beneficial effect on gross scarlet fever mortality and that proposition I ventured to dispute. Now hospital isolation can only lower gross scarlet fever mortality either by generally reducing the incidence of the disease and thereby curtailing the number of fatal cases, or by supplying hospital patients with treatment of superior efficacy to that obtainable at home, or by a combination of these two accomplishments. In your article you set aside the first claim—"the statistics quoted above seem to suggest that its prevalence does not appear to have declined notably"—but, on the contrary, in your reply to me you assert it—"The most obvious advantage of isolation is to check distribution of disease and thus to reduce the number of cases and consequently of fatal cases." These statements seem to me to be mutually exclusive. The reason for which I compared home and hospital treatment was merely to show that on such evidence as was at hand there could be no claim for distinct superiority in favour of the latter. So that if isolation hospitals do not appreciably limit the prevalence of scarlet fever, and if they do not provide appreciably better treatment than is obtained at home, they cannot appreciably affect gross scarlet fever mortality. Dr. Willoughby will, I am sure, excuse me if I point out that after citing the figures, comparing home and hospital mortality, I said, "There is a certain selection acting against the hospital of course," an expression designed to cover precisely the conditions he gives in detail.

But, apart from the point at issue, Dr. Willoughby seems to credit me with the desire of "doing away with the hospitals," and I gather that you suspect me of similar heretical leanings. My wish is rather to plead for the preservation of an attitude of intellectual disengagement on the whole question, not claiming more for the hospitals than evidence warrants and not unreservedly condemning them because they have not fulfilled the function prophesied for them. We are faced with the paradox that the segregation of certain infectious patients in many—indeed, in most—large towns has not been followed by any decided drop in the prevalence of the disease from which they suffer, and the chief lesson that paradox would appear to indicate is that diligent inquiry should be made into the factors which have prevented that result ensuing. I am not at all sure that Dr. Willoughby has not "got the right sow by the ear." He is able to show scarlet fever results of a peculiarly gratifying kind. To what are they attributable? Dr. Willoughby has the sanitary direction of one of the best-planned and best administered towns in England, a town where the standard of comfort and decency is exceptionally high, where overcrowding is practically unknown, where houses are well built and well drained, where slums do not exist, where employment is regular and well paid—a town, in fact, where every prospect pleases and even man is not vile. Backed by these enviable conditions, armed with a wieldy, airily situated, well-broken-up isolation hospital, entrusted with the medical supervision of elementary school children, and supported by a body of loyal medical colleagues, he is in a position to demonstrate that in Eastbourne scarlet fever is a manageable disease. To my mind, the suggestion is rather that a community framed on humane and discriminating lines may find such a hospital a serviceable handmaid in dealing with infectious disease than that viciously planned and corruptly disposed cities can reasonably hope by the wholesale provision of isolation hospitals to stay the natural consequences of flagrant sanitary errors. The two conceptions of hygienic strategy differ *totally*.

I am, Sirs, yours faithfully,

Oster Temple, W.C., Jan. 1st, 1907.

HUBERT E. J. BISS.

AMYL NITRITE IN HÆMOPTYSIS.

To the Editors of THE LANCET.

SIRS,—In the communication of Dr. Francis Hare in THE LANCET of Dec. 29th, 1906, p. 1830, anent my note concerning the mechanism of the action of amyl nitrite, the following pertinent interrogations are presented: 1. How could any contraction of the bronchial tubes express the blood from the pulmonary parenchyma? 2. Would not contraction of the bronchial tubes cause obstructive dyspnoea similar to, if not identical with, that which constitutes an asthmatic paroxysm? 3. How can the action of amyl nitrite upon systemic hæmorrhage, say from the uterus, be explained? I used the sponge as a simile in describing how blood was expressed from the lungs because the latter are of a spongy, elastic texture. It is conceded that the vagus contains fibres which can contract or dilate the bronchi. This fact has been conclusively shown by Dixon and Brodie. For the facts relating to its clinical demonstration I must refer to my several communications on the subject.¹ The dual function of the vagus fibres must be expressed on two kinds of muscles. Anfrecht² has shown that the belief of only a circular layer constituting the musculature of the bronchi is wrong and that by using the Biondi-Heidenhain stain a longitudinal muscular layer also exists. If our conception of the bronchial tubes were limited to the relatively rigid cartilaginous structures it would be difficult to understand how their contraction could express the blood from the lung parenchyma. Our conception of the tubes, however, is strictly in accord with the anatomic understanding. They are tubes until they end in the smaller subdivisions of the lungs called lobules and they contain muscular fibres even after the cartilaginous element is lost. The primary effect of amyl nitrite inhalation is to dilate and the secondary effect is to contract the lungs by virtue of its action on the longitudinal fibres. In the latter sense the action is tantamount to forced expiration, such as is observed in Valsalva's experiment whereby the lungs are emptied of blood. That amyl nitrite should have a specific action on the longitudinal to the exclusion of the circular fibres is not phenomenal. We have our angiospastics and our angioparalytics, and we possess myotics and mydriatics. Assuming that amyl nitrite anæmises the lung superficies, how is this effected? To attribute such action to the direct effects of the drug on the pulmonary vessels would be wrong for two evident reasons. The drug is a vaso-dilator and to admit that its action is one of vaso-constriction on the pulmonary blood-vessels is to create a theory which has no precedent in pharmacodynamics. True, we possess drugs which have a localised action either as vaso-dilators or vaso-constrictors, but when such action is expressed elsewhere it is either by dilatation or constriction of the vessels. In the blood-vessels of the lungs the influence of the vaso-motor nerves is minimised. In hæmoptysis the genesis of the bleeding is from veins as well as arteries. While Mall has demonstrated a vaso-motor influence on the portal vein such influence on the pulmonary veins is a matter of conjecture only.

In answer to the second question, I will say this, that we must differentiate the action of the circular and longitudinal muscular fibres of the bronchial musculature. My theory of asthma³ is the modified spasmodic theory. It assumes that the theory of asthma must not alone be based on a spasm of the circular but on the inability of the weaker longitudinal fibres to expel residual air imprisoned by the circular fibres. This action has its analogue in the bladder musculature when, in consequence of a spasm of the sphincter vesicæ, the weak detrusor vesicæ cannot expel the urine and ischuria spastica results. The hypodermic use of adrenalin chloride is often more efficacious than morphine in subduing an asthmatic paroxysm. Such an injection, even in a normal subject, will translate a percussion sound of resonance into dullness or even flatness—in other words, the action of adrenalin is on the longitudinal fibres and provokes the lung reflex of contraction. There is a secret remedy used in the United States which is phenomenally efficacious in aborting asthmatic attacks. It is used by means

¹ New York Medical Journal, June 13th, 1896; American Medicine, March 1st, 1902; Philadelphia Medical Journal, Sept. 28th, 1900; American Medicine, Jan. 3rd, 1903; Diseases of the Lungs and Pleura, 1903, p. 60.

² Deutsches Archiv für Klinische Medizin, Band XLVII, Hefte 5 and 6.
³ The Medical News, June 2nd, 1904; American Medicine, Jan. 3rd, 1905.

of a nebuliser. All chemical analyses of the preparation in question are untrustworthy, for formulae made according to such analyses do not show the effects of the original preparation. I have sought to determine the nature of the secret remedy by studying its physiologic action which is essentially as following: When sprayed into the nose, even of a normal subject, there is almost an immediate translation of the normal lung resonance to dullness or flatness (lung reflex of contraction). The weakness of the longitudinal fibres is also demonstrated by my tracheal traction test,⁴ which is a simple method of recognising an asthmatic lung. In accordance with the theory propounded, I treat my asthmatics in the paroxysmal and interparoxysmal periods by respiratory exercises which tend to strengthen the longitudinal fibres. I have known asthmatics whose attacks resisted even the influence of an anæsthetic for hours and which yielded after a few minutes of systematic compressions of the thorax during expiration.

Relative to the final question, I believe it has already been answered. Amyl nitrite acts on the fibres of the uterus with secondary constriction of the blood-vessels, just as it acts on the longitudinal fibres of the bronchial musculature and in the former action it is essentially an oxytocic. The lowering of the blood pressure must also be taken into account as cited in my previous communication.

I am, Sirs, yours faithfully,

Paris, Jan. 2nd, 1907.

DR. ALBERT ABRAMS.

GAS FIRES.

To the Editors of THE LANCET.

SIRS,—I have already discussed the report of the Coal Smoke Abatement Society in the columns of the *Gas World* (Dec. 8th) and whilst agreeing with some of the conclusions arrived at by Mr. Francis Jones as to the inadequacy of hasty tests carried out in larger rooms than ordinary living rooms, I must respectfully protest against his urging the results he himself arrived at six years ago as being of any greater value than those he now impugns. In March last Mr. Jones was good enough to send me a copy of his pamphlet, "The Air of Rooms, &c.," and in a correspondence which ensued therefrom I pointed out that the room in which his tests were made erred considerably on the side of being *too small*, being only of 935 cubic feet capacity. In this room Mr. Jones used a gas fire the consumption per hour and the pressure of which he never took the trouble to inquire. It had eight bunsens, and as each would consume five cubic feet of gas it was obviously too large for the room in which the tests were made. I gathered from his letters that the gas fire was fitted into the same flue as the coal fire without any consideration as to the satisfactory carrying away of the products. Upon the point of fixing Mr. Jones, in a letter dated April 7th last, said:—

I made no suggestions but wished the fire to be arranged the same way these workmen are accustomed to do in ordinary Manchester houses; if there were a more perfect way it would not suit my purpose since I wished to test the fire in the way it is commonly used.

Where such an indifference is displayed is it reasonable to publish broadcast results the value of which might absolutely be nullified by the single mistake of a workman or gas-fitter? If one is seeking after scientific truth it is important that nothing be left to the frailties of even corporation gas-fitters. Far from the fire being fitted in "the ordinary way" one can only describe both the method of procedure, the size of the fire, and the dwarfed room as most extraordinary.

Although Mr. Jones took records of the temperature of the room he did not think them of sufficient importance to publish in his pamphlet! The following are extracts from my last letter dated April 11th, 1906, to Mr. Jones on this subject:—

A coal fire can be no better ventilating agent than a gas fire if, in the latter, we generate as many units of heat as are generated in a coal fire. It is all a question of arrangement between the method of heating and the method of carrying off the products or promoting draught.

You do not think the size of the room will make any difference seeing that the experiments were comparative you might as well put a gaslight or gas fire into a hermetically sealed box, and because the oxygen gives out assert that it is conclusive proof that gas is extremely poisonous and ought not to be used. My point is, that the size of the room compared with the type of stove or method of gaslighting used has everything to do with it, and when one is correctly adjusted to the other, the carbonic acid can be kept below 10 parts in 10,000.

⁴ Ibid.

The fire used would be consuming anything from 35 to 50 cubic feet of gas per hour, whereas for a room of that size satisfactory heating would be accomplished with a gas fire consuming not more than 8 to 10 cubic feet per hour. I must say that if you had been endeavouring to get the percentage of carbonic acid in the atmosphere as high as possible you could not have adopted better conditions than a room far below normal capacity, and a fire far above normal consumption (and probably badly fitted to the flue) for your purpose.

Mr. Jones hopes the Coal Smoke Abatement Society will continue its tests. May I, too, express a similar hope—i.e., that Mr. Jones will revise his own tests, using normal conditions from which to make deductions intended for wide publication? I would not have troubled you with this letter were it not for the fact that our competing friends the electricians make as much capital as they can from such letters as the one from Mr. Jones, as is evidenced by an editorial thereupon in the *Electrical Engineer* of Dec. 21st in which appears the following summing-up:—

We think it will be admitted that the evidence which Mr. Jones produced in support of his statement was convincing proof of its accuracy, while his criticism of the society's report is fair and reasonable.

Whilst I would be the last man in the world to impute other than the highest motives to Mr. Jones, I could not, in April last, accept his own statement of his own investigations as convincing proof of their accuracy, nor am I yet able to see eye to eye with the editor of the *Electrical Engineer*, to whom, doubtless, "the wish is father to the thought."

I am, Sirs, yours faithfully,

JNO. HY. BREARLEY,

President of the Manchester District Institution of Gas Engineers.

Dec. 24th, 1906.

TUBEROSE SCLEROSIS OF THE BRAIN.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 8th, 1906, p. 1583, appeared a description, by Dr. Margaret B. Dobson, of a case of tuberoze sclerosis of the brain. On Dec. 22nd, 1906, you commented upon this paper in an annotation in which you call attention to the presence in this patient of the "rare skin affection known as adenoma sebaceum." As Dr. A. W. Campbell's work is apparently unknown to Dr. Dobson and is not mentioned in your note I venture to call the attention of your readers to his paper in *Brain*, 1905, p. 382. Here they will find a full account of this curious pathological condition accompanied by a complete microscopical examination of the brain and other parts, including the kidneys, from a typical instance of this disease. His paper contains a list of the principal papers that have been written on this subject.

I am, Sirs, yours faithfully,

Jan. 3rd, 1907.

THE EDITOR OF "BRAIN."

SOME CASES OF ORCHITIS PAROTIDEA OR TESTICULAR MUMPS.

To the Editors of THE LANCET.

SIRS,—In the early part of last November, and within 48 hours of one another, I had under my care four cases of acute orchitis. Each case presented practically the same symptoms—rigor, high temperature, nausea, and a painful swelling of one testicle. There was no history of injury, no urethral discharge, and no swelling of the salivary glands. The disease lasted from 14 to 21 days and then disappeared. The parotids escaped from first to last. It was clear I had to deal with a specific infectious disease, an acute epidemic orchitis. I had no suspicion at the time that I was dealing with the virus of specific parotitis. Two days after I had seen my first case I was called to see a man who had had rigors, a high temperature, and who was now suffering from acute orchitis. A glance at his face showed the characteristic swellings under the lobes of the ears. This case, of course, suggested the true nature of the epidemic.

Orchitis as a complication of mumps in the adult male is a frequent complication. I have known cases in which the orchitis developed before the parotitis. But I have never seen cases of testicular mumps in which the parotids entirely escaped. On consulting Osler's "Principles and Practice of Medicine" (third edition, p. 91) I find that he says, "In rare instances orchitis may be the only manifestation of the infection."

I send you this note to call attention to a simple everyday disease which for some unexplained reason may present

itself in one of its rare manifestations and may thus cause considerable anxiety with the possibility of an erroneous diagnosis.

I am, Sirs, yours faithfully,

JOSEPH A. W. PEREIRA, M.D. Brux.,

L.R.O.P.Lond., M.R.C.S.Eng.,

Exeter, Dec. 13th, 1906. Medical Officer, Exeter City Workhouse.

A NEW METHOD OF PROTECTING THE SCALP OR SKIN FROM THE X RAYS.

To the Editors of THE LANCET.

SIRS,—Whilst working with the x rays in St. Mary's Ringworm School, Eltham, there appeared to me very great difficulty in exposing contiguous areas of tinea accurately to the x rays. The methods of using circular lead glass tubes or sheet lead invariably left small sections of scalp untreated between the diseased areas. To obviate this it occurred to me to apply to the head a plastic mass, impermeable to the x rays, leaving only that portion of the scalp exposed to the rays which it was desirous to treat. Accordingly, I began to experiment with plasticine, the material with which children model. To this plasticine I added the salts of different metals and even the powdered metal itself in varying proportions, to see if I could make a mass impermeable to the rays; when I had succeeded in obtaining it the mass was so dry that it had lost all its plasticity and was useless. I found, however, a suitable substitute in a lead putty, merely ordinary putty with a fair amount of red lead added; this, even in a thin layer, was impermeable to the rays, which I was able to prove by covering the free end of a lead glass tube with it and using the fluorescent screen. To use the putty I roll out a sheet of it about 15 inches square and a quarter of an inch thick; this I place on the patient's head, moulding it smoothly over, then with a blunt spatula I remove a window over the area to be treated and no matter how irregular in shape this space may be the hair epilates uniformly after exposure to the rays and no untreated or over-treated sectors occur.

I shall be very pleased to show this method to anyone interested in the x ray treatment of ringworm or allied diseases, and if any difficulty is found in making the putty it can be obtained from Mellin and Co., chemists, High-street, Eltham, London, S.E.—I am, Sirs, yours faithfully,

JOHN D. RICE, M.B., B.Ch. R.U.I.

New Eltham, S.E., Dec. 28th, 1906.

MEAT DIET AND THE TEETH.

To the Editors of THE LANCET.

SIRS,—In his letter in THE LANCET of Jan. 5th, p. 51, Dr. J. Sim Wallace points out that some facts mentioned in my paper to the Pathological Society of London have a bearing on an important and keenly debated question in dental pathology and he asks for a fuller statement of the observations and conclusions drawn from them. In the first place, I desire to point out that any credit which may be due for the observations on the teeth referred to at that meeting and reported in your issue of Dec. 29th, 1906, p. 1777, should be given to G. W. Watson, L.D.S., and Dr. J. H. Gibbs, who made the investigation and gave a demonstration of their results to the Physiological Society in June, 1906.

Two series of observations were made into the state of the teeth in meat-fed rats. In one series young rats when weaned were fed on an ox-flesh diet, this régime being continued for from five to eight months; eight animals were employed for this investigation, an equal number of bread-and-milk fed subjects from the same litters being taken as controls. The second series comprised the progeny of meat-fed rats, 30 in number, with a like number of controls; the ages of these animals, which were also fed on an exclusive meat diet, ranged from one day to three months. The methods of investigation were: (1) a naked-eye examination of the size and general appearance of the teeth; (2) grinding down the teeth and submitting to microscopic examination; and (3) comparison of the histological appearances of the decalcified tissues. All the teeth examined in the meat-fed and bread-and-milk-fed animals alike appeared perfectly normal with three exceptions. One of these was a meat fed animal and two were control bread-and-milk-fed subjects. These showed developmental defects, which, Dr. Gibbs informs me, are identical with those frequently present in the teeth of

children, in whom they constitute a strong predisposition to caries.

The conclusions drawn from these observations are as follows: (a) The great increase in the consumption of meat in the past 50 years, to which I have recently drawn attention, is not an important factor in the development of dental caries, the increasing prevalence of which was proved by the recent investigation by a departmental committee; and (b) in view of the deficiency of lime in the meat diet and of the imperfect development of the osseous system generally under this régime, as described in THE LANCET of Dec. 8th, 1906, the results of this research to my mind conclusively negative the view that a deficiency of lime salts in the dietary makes the teeth susceptible to caries. Dr. Sim Wallace is therefore right in assuming that the facts ascertained from this research support his teaching on this subject.

I am, Sirs, yours faithfully,

Edinburgh, Jan. 6th, 1907.

CHALMERS WATSON.

THE USE OF CLAY IN SURGERY.

To the Editors of THE LANCET.

SIRS,—Respecting the annotation in THE LANCET of Jan. 5th, p. 44, on the use of clay in surgery, may I say that in 1865, when I was dresser in Lord Lister's wards, a sheet of pure tinfoil and a thick layer of "antiseptic putty" were used as the ordinary dressing to surgical wounds of almost all kinds.

I am, Sirs, yours faithfully,

Worcester, Jan. 7th, 1907.

T. BATES.

THE CASE OF MR. PEERS.

To the Editors of THE LANCET.

SIRS,—Please permit me to offer my sincere thanks to all who have expressed their disapproval of the county court judgment and their sympathy with me in such a kind and acceptable manner. The amount I have received (£35 6s.) will practically reimburse me, but I value far more the generous feeling displayed towards me by my fellow practitioners and by the distinguished men who have joined with them in their expression of sympathy. To them and to you, Sirs, for placing your columns at my service I once more tender my grateful thanks.

I am, Sirs, yours faithfully,

T. H. PARKES PEERS.

Surrey-square, Old Kent-road, London, S.E.,
Jan. 7th, 1907.

THE TREATMENT OF INFECTED EARS.

To the Editors of THE LANCET.

SIRS,—As an old advocate of conservative methods in the treatment of infective otitis I am interested in Dr. F. Spicer's letter. Of course, many cases of suppurative otitis will recover after a partial operation on the membrane with subsequent efficient attic irrigation. The membrane often heals, sometimes too readily, for one should be sure that the cavities are disinfected before allowing it to close; and this is by no means easy to be sure of. I have always taught that every case should be treated on its merits and some cases require no operation at all. But I have seen many cases in which unsuspected mischief has been progressing behind a healed membrane, and, except in comparatively recent cases, I believe it to be the safer practice to remove the membrane completely. Some time back I performed a post-mortem examination on a case of meningitis. In this case both membranes were entire but there was caries of the attic roof the result of old middle ear disease. My other point is that, as Mr. M. Yearsley points out, the hearing is often far better after removal of the membrane. Some years ago I showed a number of patients with good hearing who had had both membranes completely removed. I could have shown at the same time several patients who had apparently recovered with healed membranes. More than one of these latter cases has since developed symptoms requiring operation. Removal of the membrane will sometimes restore hearing in advanced cases of chronic progressive deafness. Yesterday a lady came to see me whose left membrane I removed in 1904. At that time she was absolutely deaf in the left ear in spite of much advice. She can now hear a sermon in church, though the right ear, which was also affected, is now absolutely deaf.

She tells me that the hearing improved more during last year than in 1905, an interesting fact in opposition to the predictions of more than one otologist.

I am, Sirs, yours faithfully,
Jan. 5th, 1907. F. FAULDER WHITE.

GASTROSTAXIS.

To the Editors of THE LANCET.

SIRS,—In his interesting address on Gastrostaxis published in THE LANCET of Nov. 3rd, 1906, p. 1189, Dr. W. Hale White refers to 29 cases which he has collected. May I draw attention to another case in which I operated, published in the *Intercolonial Medical Journal* of Feb. 20th, 1901? This patient was diagnosed as suffering from gastric ulcer at the Prince Alfred Hospital, Sydney, as well as by two physicians at St. Vincent's Hospital, Melbourne, was operated on, and died, and post mortem no lesion could be found anywhere in the alimentary canal from oesophagus to rectum, or in any abdominal organ. Another unpublished case was the following, seen on July 18th, 1906, with Dr. Alan Mackay and Dr. W. A. Wood. A married lady, aged about 30 years, had for several years been subject to very severe attacks of hæmatemesis with epigastric pain. In several of these she was so collapsed as to be apparently on the point of death. In spite of treatment and most rigid dieting the attacks recurred at varying intervals. The possibility of gastrostaxis was considered and mentioned to the patient and her husband but gastro-enterostomy was advised and performed. The interior of the stomach was very thoroughly examined, the mucous membrane being protruded through the gastric incision, but no ulcer or other lesion of the mucous membrane could be found. On the second day after the operation she developed acid intoxication with symptoms exactly like those of diabetic coma. The urine contained no sugar but traces of diacetic acid and much indican. She died on the third day after operation. Unfortunately no post-mortem examination could be obtained.

Melbourne, Dec. 4th, 1906.

I am, Sirs, yours faithfully,
G. A. SYME.

HOSPITAL REFORM AND THE CLERGY.

To the Editors of THE LANCET.

SIRS,—I have been reading with much interest your article on hospital administration and reform. As you point out, the root of the evil lies in the fact that large numbers of people have come to expect free treatment as a right and that charitable persons insist on a return for their subscriptions in the shape of a subscriber's letter.

Now these are two serious faults which can only be checked, not cured, by the appointment of almoners. An alteration of public opinion on these points is needed and it can be effected by no body of men so well as by the clergy. It seems ridiculous that we should often have to spend a large part of our time in making the necessary inquiries before signing a letter, doing work that an almoner at the hospital could do so much better, while all the time we are neglecting the teaching of self-reliance and of higher ideas of charity which certainly should be part of our duties. May I suggest, therefore, that every member of the medical profession should do his best as occasion serves to bring this matter before individual clergymen, pointing out to them the waste of their time and the harm of the present methods while urging them to preach higher conceptions of social duty?

But I have a further object in writing. It is not merely that I grudge the time we have to spend in making inquiries before signing letters, and regret the abuse of the hospitals where such inquiries are not made; I regret even more the fact that we clergy are looked upon by the working-classes as mere amateur relieving officers. I am convinced that so long as there is any expectation on the part of the poor that they may receive material help from us our real spiritual work is ruined. I see no chance of any great spread of religion among the masses till it is entirely separated in their minds from the receiving of relief. If medical men will point out to us that in working for hospital reform we are making possible our own special work, each profession will be helping the other for the common good. But there is a mass of false opinion on the subject which will only be altered if each individual medical man

will approach each individual clergyman whom he knows with the object of converting him.

I am, Sirs, yours faithfully,
(Rev.) CLEMENT F. ROGERS.

Southampton-row, W.C., Dec. 23th, 1906.

WEST AFRICAN MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—A month or two past I read a letter in THE LANCET contrasting the West Indian with the West African Medical Service rather to the advantage of the latter. Perhaps in writing to give you a few of the real facts, about the conditions out here I may be doing a service both to the members of the West African medical staff, of whom I am one, and to anyone who, knowing no more of the matter than he can learn at the Colonial Office, may think of coming out here and benefiting himself thereby. Economy—on paper—is the fashionable watch-word of the administration at present and it is with economy as practised at the expense of the medical service that this letter chiefly has to do. The ordinary person at home would naturally think that in a climate such as this the medical officers would be people of considerable importance, well paid, well equipped, and with every facility given them for the proper performance of their work.

Let us contrast this with the facts in being. In the first place, there are never enough of us on the coast to supply all the stations. I think I may state as a fact that every station has never been in possession of a medical officer at one and the same time, and some stations have been without any medical officer for months at a time, not once but two or three times in my own experience. There may be a station in Southern Nigeria which is fully equipped with surgical instruments, drugs, and appliances, but though I have been stationed in several places and have discussed other stations with their medical officer I have yet to meet or to hear of one which at all nearly approaches that standard. Many I know have a few old knives and scissors, probably some antiquated tooth forceps, and a post-mortem case, as their equipment for looking after the lives of white men. I have never seen an ophthalmoscope, a liver-abscess outfit, a case of eye instruments, or a case of sounds for stricture—to mention a few out of many absent important instruments provided in any station. That these and other necessities have been applied for times without number I know well, the answer given being that the huge vote of £1000 a year for drugs, instruments, and sundries for some 80 stations will not cover such expenditure. Many men bring out their own instruments rather than be called upon to face an emergency without proper tools. As to drugs and appliances, one's requisition list is usually shorn of all that is individual to the man making it, and every medical man knows what it means to be without the drugs which he is particularly fond of, and I know of a case where the item of two towels and two dusters for hospital work were out of a requisition, the result being that the medical officer had to use his own or do without; he did the former. There may be military expeditions on which a medical officer is equipped with an amputation case and a bullet extractor; I daresay there have been but I know of two cases where neither of these necessities was included, and one of these expeditions lasted over five months. In this last instance the medical officer applied for a trephine; it was refused with instructions to send any patient needing such an instrument to the nearest big station. Oddly enough, a case for trephining did occur, and the patient was sent to the nearest big station, with a loss of time of six days and, curious as it may seem, that station had not got a trephine either.

Before we come out here the Colonial Office pays for a course of instruction at the London Tropical School of Medicine; the value of this instruction is, however, greatly discounted by the extreme difficulty experienced, in spite of the bold assurances given at the Colonial Office, in getting a microscope allotted and sent to one. Economy does not allow the natural remedy for this of keeping a microscope at each station. Numbers of cases are extant of a microscope being supplied in, say, the eighth month of the tour (it sometimes comes as early as the fourth or fifth), while the slides, stains, &c., did not reach the applicant till just before he was going on leave. A hospital for Europeans in every large station would seem a necessity to the ordinary person and there is one I know in South Nigeria and I know of another one

building. But how many lives have been thrown away by there being no hospital accommodation, which is almost universally the case, and how many people have been invalided for the same reason one cannot say, but the number of European officers who die on the way home and in the first three months after their arrival in England must be added to the Government death-rate to get an idea of the reality.

How can a medical man do his ordinary work and nurse a couple of serious cases day and night—one very likely in his own bed—and do the work properly? It is impossible, even leaving out of the question the danger to his own health and life, but it is done out here constantly and "economy" is supposed to justify it. I know of a case where a European hospital was down and passed in the estimates for 1906 and the building was not started till the middle of October; the reason given—I cannot vouch for the truth of it—was that the governor wished to choose the site on the occasion of his annual visit, and some colour is given to this by the fact that he did choose it and a different site from that previously selected by the medical officer of that station. Another instance of economy in connexion with that hospital is that the balcony verandah was originally designed 10 feet wide all round and economy in the shape of the governor cut this down to 9 feet at the sides and 6 feet at the ends.

And now as to the pay. A medical officer gets £400 a year, rising to £500 by yearly instalments of £20; a small percentage pass on if they survive to the giddy height of £800-£700 a year as a senior medical officer, of whom there are three or four, while £800-£900 is given to the deputy principal medical officer and £1000-£1200 to the principal medical officer. Considering the importance of the medical man in this climate let us contrast this with the pay of other professional and non-professional men. Senior district commissioners, £600-£700; ordinary district commissioners, £500-£600; police magistrates (professional), £500-£600; puisne judges (professional), £1000; Solicitor-General (professional), £700-£900; superintendent of telegraphs, £500-£600; marine superintendents, £500-£600; superintendent engineer, £600-£800; engineers, £400-£500; assistant conservators of forests (recruited from anywhere), £500-£700; provincial engineers, £600-£800, and so on; somehow the medical man does not rank very high, but this is not all.

Up to May 1st, 1906, the medical officer as a second class officer (a matter of size of salary) was entitled to a travelling allowance of 15s. a day in common with all officers of his standing. In connexion with the amalgamation of Southern Nigeria and Lagos travelling allowances have been cut down to 5s. a day for officers of that grade, but a compensating allowance called "duty allowance" varying in amount from £80 to £300 has been granted to every officer of that or higher standing except the medical officer. The excuse for this "economy" is that the medical officer is allowed private practice. Private practice in the majority of stations does not exist, and where it does has not a medical man the right to money earned after Government work is done in the exercise of his profession without a deduction from his salary being made! Much of the work would have to be done whether the Government liked it or not.

Up to last year medical officers had an allowance of £50 a year for doing public health work and many of them took a course in public health and a diploma to enable them to do the work well. Last year an attempt was made to remove this shocking piece of Government extravagance altogether, but a few men were not to be bluffed and finally the allowance was continued in the case of men who had joined the service before Jan. 1st, 1905. Medical officers appointed after this date do not get the allowance, but are, of course, expected to do the work, and equally, of course, they have to submit to having their work criticised and in some cases altered by political or even by army officers or other laymen who, of course, know much more of sanitation than does a medical man. Practically, then, the medical officer is the only person to suffer by this economy, certainly the only professional man, and this surely ought not to be.

Can your influence, exerted perhaps in Parliament, alter, or help to alter, this condition of things? At first? If nothing else can be done, a warning to medical men contemplating joining this service to get black and white (economy is still going on, "rigid" is now pressed in official documents) should do good, so that if

they join at all they do so with their eyes open, knowing that their living wage cannot be further reduced. Moreover, we think that if they have a full knowledge of the state of things the better class of medical man will not offer himself for this service, which will make the Government treat us fairly, as if the class of medical officer goes down the class of other employees will go down too, the best class of men not caring to risk their lives unnecessarily.

I am, Sirs, yours faithfully,

A WEST AFRICAN MEDICAL OFFICER.

THE ARMY: PROJECTED CHANGES, MATERIAL AND MORAL.

To the Editors of THE LANCET.

SIRS,—In a leading article in THE LANCET of Dec. 15th, 1906, p. 1673, you criticised Mr. Haldane's recent address to the members of the committee which he has called into being to advise the Army Council in matters affecting the spiritual and moral welfare of the army. As you observed, Mr. Haldane's meaning was occasionally elusive and there was much that was nebulous and indefinite in his speech, but at the same time none can deny that Mr. Haldane is probably more capable of clear reasoning and definite expression than the majority of his colleagues in the Cabinet. Perhaps as a philosopher accustomed to the guidance of pure reason he felt a little uncertain as to the terms in which an audience composed principally of ministers of various religious denominations should be advised and as to what topics should be especially recommended for their consideration. Possibly he may have felt that, as you expressed it in your article, "the committee is cut off from a valuable source of information by not containing a medical member." His words when read carefully seem to suggest this, for he said among other things, "nowadays it is realised that you cannot save men's souls without attending to their bodies, and, conversely, it is considered that all cannot be well with their bodies unless it is so with their souls also." In another passage he referred to the importance of inculcating temperance, as a work demanding the co-operation of all interested; and in yet another he said, "Religion is not morality but morality and religion go together; you cannot divorce religion from its surroundings, but if the surroundings become better then the awakening of religious life becomes easier." The moral and religious aspects of a soldier's possible mental training Mr. Haldane naturally found to be inseparable, and he seemed to have on the tip of his tongue admissions that the consideration of his physical circumstances and conditions of life was also involved. Indeed, as has been said above, he referred directly to the evils of alcoholic intemperance and he also made allusion to the opportunity for moral instruction which might be found when the soldier lies sick or injured in a military hospital. At the same time the fact remains that Mr. Haldane has placed no medical man's name in the list of his committee, although it does not consist exclusively of ministers of religion, and although upon it one or more army surgeons of experience in their branch of the profession and one or more physicians of wider experience in some directions than army surgeons may have the opportunity of enjoying would have been of considerable service.

In the various circumstances of barrack life, in the feeding arrangements and in those connected with the supply of alcohol and other refreshments, in the provision of sleeping accommodation, and in sanitary matters there is much which affects physical and moral conditions simultaneously. In connexion with morality, one particular and obvious phase of the question, that of sexual morality, involves physical considerations almost impossible to eliminate from any discussion primarily devoted to the religious bearings of a difficult subject. All the above points and many others need to be ventilated and discussed not only by teachers of religion, and not only by eminent leaders and organisers of soldiers as fighters in the field, but by others whose acquaintance with the soldier is more intimate than that of the general or the bishop (or even the chaplain), and by those whose knowledge of their subject is increased and supplemented by scientific training. The medical man would have his prejudices like other members of the committee. His prejudice, for example, would lead him to oppose any movement which had as its probable result the hindering of the soldier from seeking medical advice at the earliest possible opportunity when infected with venereal disease.

In a recent paragraph *Truth* informed us that "a very

proper order has been issued by Lord Kitchener in India under which men admitted to hospital for certain reasons for which they may be rightly held responsible shall forfeit service pay for 12 months and be required to make up subsequently all guards and pickets which they have missed while in hospital and be disqualified for all paid employment." An order such as this, if it refers to the class of disease mentioned, as it pretty obviously does, might logically be considered likely to impel the soldier to seek early relief in order to avoid recourse to the hospital at a later stage, but the soldier is not logical and it is really almost certain to influence him in a diametrically opposite direction. In addition to military punishment we may now see a tendency to make the soldier ashamed of his moral downfall with a kind of shame which will come home to him when he is infected with disease but which will not prevent him from running the risk of contracting it. As a matter of fact, the effect of such an order as that outlined by *Truth* and of any shame to admit himself a victim will be, almost universally, to drive him to the quack doctor who in India no less than at home, but perhaps more so, lies in wait for a victim whose health he can undermine and whom he can bleed and blackmail to his heart's content owing to the fact that he is liable to an unbending military discipline. A medical man or two with knowledge of the natives and native doctors of India, of the soldier's ways in the "Shiny East," of the leisure on his hands there and of the difficulty which he has in killing time, of the temptations of the bazaar, and of the ways of the native women who may come in the soldier's way outside the bazaar, would be of use as witnesses if the committee is going to call evidence; and in any case would be highly desirable as members of it.

It will be interesting to note if any conclusions are arrived at unanimously by a committee consisting so largely of religious teachers of different sects. The bishop in India, and, I believe, at home, has considerable authority over the army chaplain, and the army chaplain's performance of what he conceives to be his duty at times leads him to do what is not in the rubric, so that he is brought into collision with a bishop whose knowledge is of the rubric rather than of the soldier. The committee contains many other elements not to be described as homogeneous. Will these fuse themselves because they sit side by side round the same table, or will the committee meet slightly more of a mundane element to render its deliberations of practical usefulness? From what point of view, for instance, will they discuss the marriage question and what will they say about it? It has its physical and medical aspects and the restrictions on marriage in the army are at the bottom of much of the sexual immorality and venereal disease in it. Will the committee agree to say anything on this topic and, if it does, will what it says be listened to? Or will it say very little and will its observations, if any, be politely filed and forgotten? The matter is one of great interest. The moral atmosphere of the army is such as to keep out of it many thousands who would make good soldiers or to inflict upon them if they enlist intolerable pain and discomfort, often moral deterioration and degradation. It is to be hoped that Mr. Haldane intends to make an experiment of a genuine character, and if anyone can make it a useful one he can. That the *personnel* of the committee might be improved upon will, however, occur to many.

I am, Sirs, yours faithfully,

LOOKER-ON.

Jan. 7th, 1907.

THE HYGIENE OF CHILDHOOD IN GERMANY.

(FROM A CORRESPONDENT.)

IN April and May of last year a short course of training for those engaged in the administration of charity and especially in the care of young children was held at Frankfurt. Ten years ago a private citizen founded an institution called the "Zentrale" for the administration of charity and the direction of charitable endeavour. While coöperating with existing institutions the new one struck out for itself in various directions. It gave much attention to infant mortality, it arranged holiday colonies, widowers' homes, and maternity insurance clubs, and made arrangements for the better teaching of invalid cookery. The Swiss Federal Government, invited to send a commissioner, chose Dr. Zollinger, whose report on school hygiene at the Paris

Exhibition of 1900¹ attracted so much attention. Dr. Zollinger's report on the Frankfurt Congress is before us. It is entitled, "Probleme der Jugendfürsorge," and is published in the Year-book of the Swiss Society of School Hygiene.²

Stated briefly, the report deals with the whole problem of the production and treatment of the unemployable (*Die Sozial-Unbrauchbaren*). The state of civilisation of a nation can be judged by the means taken to deal with this problem. It must not be taken for granted that it is good for a nation to rely on foreign importations for its supply of unskilled labour or that social inequality can be redressed by the simple act of giving money. The best way of giving relief is to measure the social capacity of the individual and to teach him to make the most of it. If he does his best and yet cannot support himself he must be assisted, but in this case no moral stigma attaches and no moral evil results. Frankfurt is a city of Jews, and the Jews have always borne a good name for the care of their mothers and young children. It is not surprising to find that the care of the bearing mother is the first object of the association. A maternity club is in operation which performs the heavy housework for the expectant mother and grants her sick pay during the period of lying-in. Sometimes this help is insufficient, the weekly wage may be stopped or too small to maintain the family in efficient capacity for work. In these cases further help is granted or obtained. Many women to whom a maternity home would be of great service refuse to enter one as they do not care to be the subjects of clinical instruction. Herein the wife of the lower middle-class suffers most. The working woman has no compunction in seeking aid at an institution but the small trader's wife tries to manage her home while she is lying-in. The establishment of a maternity home, without clinical instruction, where the mother can be treated at the rate of her sick pay, is considered a most desirable aim. The working woman is already protected by statute from factory labour for six weeks after delivery but she is not forbidden to do work at home, whether housework or for wages, and this can be prevented by offering her maintenance under conditions which will free her from worry.

In Berlin there is an Association for the Protection of Mothers which publishes a periodical called *Mutterschutz*. But there is a great objection to loose sheets which are easily lost. In some towns a mother is supplied with a pamphlet of instructions, dealing with the care of young children, on registering a birth. This pamphlet also gets mislaid. The best plan is to issue a calendar on cardboard, with rules for a mother's guidance. Such a calendar can be obtained from Hermann Meyer (Frankfurt-am-Main, Bleichstrasse 23). It gives a tear-off calendar with 12 golden rules for mothers on the sides. The first of these is, "Nurse your child yourself." The subject of breast-feeding of infants is becoming of first importance in Germany, where the Kaiserin has given so much patronage to the endeavour to check infant mortality. Professor Mayet, whose views are quoted on pages 23 and 24, advocates that each mother should be put on sick pay by her club for 12 weeks, the pay to begin six weeks before the time of expected delivery. Further, that a premium of 25s. should be paid to a mother nursing a child for six complete months and a further 25s. for each child nursed for a whole year. He demands that maternity insurance, which is optional in sick clubs, should be compulsory, not because the woman is unable to perform her work properly but because heavy work before delivery is injurious to mother and child. If workmen's insurance be extended in this manner then two-thirds of the births in the German Empire will take place under hygienic and sympathetic conditions and the mortality of infants will receive a severe check. But if a mother is to suckle her child she must be well fed. This means the establishment of a special cuisine for nursing mothers and the supply of suitable food ready prepared for mothers who work in factories. For these women a crèche should be established at or near the factory to which they should have regular access.

Dr. Zollinger gives a detailed description of the arrangements made at Marburg for the care of unweaned children and the supply of milk products to parents (pp. 43 to 57). The Marburg Institute is divided into three departments—one is a home for infants, the second is for the preparation and sale of milk products, and the third is for the supply of

¹ Bestrebungen auf dem Gebiete der Schulgesundheitspflege, Orell Füssli.

² Zürich:

milk. In the milk kitchen all kinds of milk diets are prepared according to prescription and they can be bought on a medical man's order. What is of interest, however, is the list of rules for the conduct of the dairy. All cows are vaccinated with tuberculin. They are inspected every six months by the veterinary surgeon and revaccinated at least every year. Strict regulations are in force as regards the stalls, bedding, fodder, water, and milking utensils. The milk is tested on delivery at the kitchen for fat and once a week in the bacteriological laboratory. Cows are milked twice a day. Before milking, the operator must wash the udder of the cow and his own arms and hands. He may not begin till the stall is thoroughly clean or operate directly after a dust has been created. The first milk must be drawn out on the floor. The milk-pail must have a small opening and, inside this, a strainer consisting of a boiled cloth must be fixed. It is not improbable that in the near future a separate stall, with glazed tiles and washable floor, will be erected in which all milking will take place. In this stall the hose will be in frequent operation. The products sold are prepared in accordance with the infant's requirements. Dr. Effer of Dantzic has shown that the use of cows' milk causes more than three times the amount of illness and about four and a half times as many deaths as occur among breast-fed children. Professor Mayet calculates the protective power of breast feeding as reducing the mortality by 80 per cent. He considers that the adoption of breast feeding will be ultimately worth 28,000 men annually to the German army. Dr. Rösé of Strasburg asserts that the longer a child is breast-fed the less likely is he to suffer from dental trouble and rickets, and the more fitted he will be eventually for military service. The constant appeal for military *Tauglichkeit* (fitness) is the least pleasing feature of the agitation. But the German knows his own people best and must select the motives on which to work.

The attention given by Dr. Zollinger to the treatment of illegitimate children, to which 50 pages are devoted, shows that these unfortunates are likely to bear less of the stigma of their birth in the future. At Frankfurt the Zentrale takes over the guardianship. In Berlin a special home is opened for girls of a respectable class who have been betrayed. These suffer most of all, for their relatives consider only their own position and are anxious to lose all sight of the girl. It is of great importance that illegitimate children should be prevented from joining the ranks of the morally abandoned and later the criminal classes. For this purpose it is usual in Germany to provide the child with an official guardian. At Leipzig he acts from birth up to the time when the child leaves school. At Frankfurt a close inspection is made of all boarded-out children. For particulars of the treatment of illegitimate children in the large towns of Germany the reader cannot do better than turn to Dr. Zollinger's pages.

Two other features of the Frankfurt organisation call for consideration. The widowers' home is an institution for working men in which a home is provided for each family. The children are cared for and fed. They spend their leisure with the father and sleep at night in dormitories. The rent of a two-roomed house is from 3s. 6d. per week; the charge for board is: for one child 3s. 6d., for two children 6s., and for each other child 1s. extra per week. On Sundays a dinner for parents is provided at 4d. per head. Workshops can be hired in the basement at moderate rents.

The treatment of juvenile offenders receives a great deal of attention in the volume. The American system of separate courts is recommended for adoption and a system of placing the youthful offender on report, or of postponing sentence, receives favourable notice. For the treatment of these interesting subjects there is no room here. Those who wish to learn Dr. Zollinger's views will perhaps be content with the following recommendations which conclude his report.

1. Courses of instruction in the care of children should be formed. They need not last more than a fortnight, but they should embrace both the theory and practice and be suited to the needs of officials and private parents.
2. In large communities, by the amalgamation of small philanthropic societies, a central institution, similar to the "Zentrale" in Frankfurt or the Zentral-Station in Berlin and Dresden, should be formed.
3. All arrangements that a mother better for her duties should receive official encouragement. In this respect the dilemma of Counselors in the care of the child begins with conception should be remembered.
4. The interest of the State in the child does not begin when the child appears at school age but on birth, and is needed most in the case of children who are in special or abnormal circumstances.

5. Special care must be given, from official sources, to illegitimate children. Official or professional guardianship should be introduced to protect mother and child and to guarantee proper medical and educational care. Guardianship should begin before birth and continue till the child has finished its apprenticeship.

6. Breast feeding should be supported in every possible manner. On the registration of a birth the mother should receive a paper of instructions on the care of infants. The parish council should undertake the supply of milk for infants. Infant nursing homes should be eligible for grants of public money.

7. The establishment of crèches, day homes, and widowers' homes corresponds to a social want. Public encouragement should be given to any scheme for meeting this want.

8. The establishment of holiday colonies, country schools, and of school clothing clubs should be encouraged. All schools should be under medical inspection.

9. The care of children is best managed, in general, by the family. But in cases of physical or mental weakness it is better intrusted to an institution.

10. An Act should be passed dealing with the subject of the protection of infant life. It should fix the age of responsibility at a minimum of sixteen and should provide for special courts for the trial of youthful offenders. It should contain some scheme for placing an offender on report or under supervision.

THE PARIS ABATTOIR AT LA VILLETTE

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

PARIS is so beautiful a town, incomparable in so many respects, always charming and attractive, that its example influences the whole civilised world, but more especially the larger towns of France. What Paris does other towns strive to imitate. This is not always an advantage. In regard to the slaughter-house question it has proved a decided disadvantage. Certainly Paris early in the history of municipal enterprise instituted public abattoirs, but in so doing it allowed the private interests of a trade to interfere with the interests of the public at large. The public slaughter-houses of Paris are vast institutions. Indeed, they have become public show places, especially the largest, situated at La Villette. Here notably a public reception was given to the members of the London County Council when they visited Paris last February. The sight was very impressive. The vast extent of the open space at the approaches of the slaughter-houses facilitated the accumulation of a large crowd and the display of military as a guard of honour. Also the abattoir covers 16 hectares (about six acres) of ground and it is a municipal institution. Viewed at a distance by non-technicians it seems to be a very vast and fine installation. In all this, however, appearances are deceptive. Paris is not setting an example to the world, and not even to France in respect to abattoirs. Paris only followed the example of the French provinces and followed it badly.

A very important work has just been published on this question. It is entitled "Les Abattoirs Publics." The first volume has 902 pages and many illustrations. The largest half of the book is devoted to cold storage and the rest to the construction of slaughter-houses and all that appertains to them. It is written by M. J. de Loverdo, sanitary engineer, licentiate of sciences of the Sorbonne, who for four years travelled in various countries on behalf of the French Ministry of Agriculture to study all that related to the question of abattoirs, meat storage, &c. The second volume of this great work, one of the greatest of the books, if not the greatest, written on the subject, has 645 pages, with many illustrations some of which are admirably coloured. The principal author of this second volume is M. H. Martel, doctor of science and chief of the sanitary veterinary service of Paris. He is assisted by M. Mallet, veterinary surgeon and director of the Argers abattoir. This second volume deals with the inspection and administration of slaughter-houses and cattle and other markets. To M. Martel personally I am indebted for a great deal of information and for his kindness in devoting much time to show me round La Villette abattoir. This was a little trying for him, I fear, as he had to confess at almost every step the imperfections of the installations and methods adopted. But these are certainly not due to any neglect or ignorance on the part of the officials. The latter have been unceasing in their complaints and protests. With the assistance of the big volumes just mentioned I am now able to describe not merely what I saw at La Villette but can also explain how the present evils arose.

This article commences a short series describing slaughter-houses in different countries, the object being to bring together materials from existing practice to form a basis for a constructive policy.—ED. L.

It appears that the butchers were a specially privileged section of the community. In the celebrated encyclopædia which so effectively contributed to bring about the great French Revolution Diderot wrote a long article under the heading "Butchers." Here it is shown that the butchers of Paris contrived to secure some of the advantages that were accorded to the butchers of ancient Rome. It was a very close corporation. The right of being a butcher was restricted to certain families and these formed a sort of aristocracy. They were very rich and able to make loans to the king and to buy privileges which exempted them from the action of the common law. It would seem, however, that the butchers ultimately made abusive use of these advantages so that their special privileges were abolished by Royal decree in March, 1719, and they then came under the common law. The Revolution in 1789 abolished all the guilds or trade corporations and then, as anybody who chose could become a butcher, abuses due to excessive licence soon arose. A decree therefore, dated the 8 Vendémiaire of the year XI., re-established the butchers' corporation and limited the number of butchers' establishments. Thus the trade won back a great deal of its lost influence. The numerous private slaughter-houses which rendered life hideous in the suburbs of Paris were abolished by law, and finally a decree was issued on Feb. 9th, 1810, ordering that five public slaughter-houses should be built at the cost of the town of Paris. Thus, if the London County Council can make very great haste and bring much pressure to bear there is just a chance that in obtaining public slaughter-houses London will not in this respect be more than about 100 years behind Paris. By the way, I know that THE LANCET is no supporter of those who are ever girding at the London County Council, if only because THE LANCET has no politics, but it is the duty of all sanitarians to insist that in the matter of slaughter-houses much remains to be done by the municipal authorities of our capital.

The city of Paris was not, however, the first to move in the matter. There had been something like public slaughter-houses in the Middle Ages, such as the *cocherie* at Amiens, built in the thirteenth century, at Lunel in 1366, and a century later at Troyes and Sommières. But what might more justly, and in the modern sense of the term, be considered as public slaughter-houses were built from 1780 to 1812 at Rochefort, Blois, Grenoble, Orleans, and other provincial towns. M. de Loverdo gives the plans of some of these abattoirs built a century ago and claims that in them will be found the prototype of the most perfect slaughter-houses of modern Germany. How is it, then, that to-day the French abattoirs are very inferior to those of Germany? The fact is that in building the first public slaughter-houses the advantages of working together in public were considered of the greatest importance. A large hall is easier to watch over, to clean, to ventilate, and to illuminate than a number of small separate compartments. Thus in these earliest of French public slaughter-houses, just as to-day in the latest types of perfected German and Swiss slaughter-houses, there are no small private killing-sheds but large, brilliantly illuminated halls where no concealment or privacy is possible. This was done in the provinces because in the smaller towns the butchers' corporations were not as powerful as in Paris. In Paris the butchers extracted a promise from the authorities that if their private slaughter-houses were abolished they should enjoy equal freedom and privacy in the public slaughter-house. Therefore the plan first proposed for a large slaughtering hall had to be abandoned and schemes prepared so that each butcher might have a small compartment entirely to himself.

The first five public slaughter-houses of Paris were erected at the Roule, Villejuif, Grenelle, Ménilmontant, and Montmartre. When first occupied in 1818 the butchers were greatly surprised to find that their habits were in nowise interfered with or altered. The plan then adopted has not been altered since. It consists of two long rows of low buildings with a court between them. Giving on to the court, which is often roofed over, there are numerous compartments something like coachhouses. At the back of each compartment there is a small door opening on to a road and there the meat can be taken away or the live cattle brought in. In front of each compartment there is a large double door which, when open, not only supplies air and light but enables the butcher to step out and do a part of his work in the court. At a distance these structures look like long, low, and broad pavilions but when seen close to

and from either end the centre appears as a great glass-roofed gallery and on the sides only is there solid masonry to wall off each butcher's private compartment. In some abattoirs this centre is not roofed over and then it appears like a thoroughfare or street.

These five ancient slaughter-houses cost the city of Paris about £800,000 and occupied 156,500 square metres of land. It is calculated that the land cost 6 francs, the building 109 francs, and interest on capital during the period of construction 13 francs per square metre. Altogether, 128 francs, or £5 2s. 6d., per square metre. The actual amount of land covered by buildings was 43,000 square metres and the cost of construction if divided by this smaller figure would amount to 395 francs, or £15 16s., per square metre of building. These figures are interesting, for they show that more than two-thirds of the land were left open and not built upon; thus such structures as did exist were amply surrounded with space, so they would be exposed from roof to floor to the direct and purifying rays of the sun. Also, it must be recognised that the earliest architects of the Paris public abattoirs studied with minute care how to provide an ample supply of water, and even in those days, when the necessity of public sewers and domestic drainage was not appreciated, still it was thought indispensable to supply the slaughter-houses with sewers. Likewise it was early felt that the ground should be protected from pollution and therefore cement and very thick pavement or flagstones were laid down wherever animals were to be slaughtered. All this was done under the direction of the Paris municipality from 1810 to 1818, the period during which the five first public abattoirs were built. This is a fact and a date that should be taken to heart by every town and borough councillor of Great Britain. Before commencing to build, the architects had studied all that was done in this respect in Italy and in Spain and this was before railways rendered travelling an easy matter and while wars were still devastating Europe. The opposition of the butchers marred their plans but nevertheless they set a great example. They created a new sanitary service, an institution which served as a model for all Europe during more than the first half of the nineteenth century.

In the course of time as the population increased and new quarters were inhabited the position of the five abattoirs became less suitable. New slaughter-houses were built and some of the old ones were abandoned. In 1860 there were ten public abattoirs in Paris. This was the time of the Hausmannisation of Paris, when so many improvement schemes were eagerly promoted. It was then decided to abolish all the abattoirs on the north side of the Seine and to replace them by one single abattoir at La Villette and close to the cattle market. Such concentration is now very generally recognised to have been a mistake. The distance that some butchers have to travel from their shops to the abattoirs is often more than four, and sometimes even six, miles. This increases the risk and difficulties of transporting the meat and has brought into existence intermediaries who have to be paid, and this increases the price of meat. Concentration of slaughtering in a public abattoir is good and necessary, but there is a limit, and one abattoir is not sufficient for more than a million people. Paris has 2,741,063 inhabitants and by far the greater half live on the northern side of the Seine. La Villette abattoir is built close under the fortification to the extreme north-east of Paris. It is approached by the broad Route de Flandre and is hedged round by the fortifications, the canal de l'Ouroq, which contains very impure water, and the canal Saint-Denis. From the main entrance in the Route de Flandre the grounds widen out like a fan. There are 20 very similar pavilions. Along the length of the pavilions run streets, like the spokes of a fan or a wheel, and across the extremities run broad tree-planted avenues.

The crescent-shaped entrance off the Route de Flandre forms the handle part of the fan. Here is a vast yard with a clock tower in the centre. The first buildings on entering are the porter's lodge and the offices of the *octroi* where the town dues are paid on the meat as it leaves the slaughter-house to be delivered to the butcher. Then standing by themselves on each side of the clock tower are two large buildings with a rotunda in the centre. One is used as an auction and sale room for meat and the other contains various offices for the different administrative services. Here are the sanitary services and I have never seen a more miserable installation. In the dingy little office set aside for the veterinary surgeons there is but one

The Paris Abattoir at La Villette. The roofed court uniting two slaughter pavilions. Each double door is the entrance to a butcher's separate private compartment. Pigs on the moveable wooden partitions show where meat is hung over the filth and manure stagnating on the floor.

no decent chairs, no books, no laboratory, and no sign of comfort or dignity. It is extraordinary that such an important service should be so badly housed. Such treatment is altogether unworthy of a town like Paris. The municipality should insist that its functionaries and officers must be treated with proper respect by being supplied with suitable quarters in which to do their work. When Sir Edwin Cornwall and the members of the London County Council went to La Villette they were received in an auction room and under a domed and lofty roof. They never saw the dark, dirty, barely furnished, and cheerless little office where the veterinary surgeons and meat inspectors do their clerical work. The visitors did see one of the slaughtering pavilions but it had been cleaned and duly prepared for inspection.

To the non-technical observer these pavilions when empty and clean are likely to produce a favourable impression. The roofed middle court has a Crystal Palace-like appearance. The visitor notes the presence of plenty of light and air. He sees that each butcher has his own private compartment, with a big double door and a little loft above to use as a storage room. It requires practical knowledge of the work to realise that inside these separate compartments there are less light, less fresh air, and none of the modern mechanical contrivances which not only facilitate the lifting and transport of carcasses but help to keep the meat free from contact with dirt. A few wooden rafters across the ceiling, an old-fashioned pulley and rope, that is all that exists to lift the heavy carcasses of horned cattle. There are no less than 216 of these private compartments in which animals are killed at La Villette, and naturally it is impossible for the meat inspectors to go in and out and watch efficaciously all these different shambles. As a result extraordinary disorder prevails. The butchers throw open their doors and do a great deal of their work in the open court, thus showing that after all there is no such very urgent reason against a common slaughtering hall. But as this court belongs to all, and to no one in particular, there is no order kept. The butchers do just what they please; so the viscera are thrown down on the ground and the stomachs or intestines are opened and emptied. Blood, manure, half-digested food, and offal collect and form a disgusting coagulum, so thick and heavy that it can only partially drain away. In Germany a visitor can inspect a slaughter-house while wearing dancing shoes; but at La Villette it is necessary to wear great heavy wooden clogs. (See illustration.)

Luckily the pavement is carefully cemented throughout all these killing places, though there are some parts reserved for the treatment of by-products where this is not done. Undoubtedly the viscera should be removed and the carcasses should not be cut up in the immediate presence of swamps of offal and manure. The necessity of cleanliness does not seem to have impressed the butchers of La Villette. There are ample light and air in the roofed courts where they do a large part of their work, but the filth on the pavement is sometimes ankle deep. So long, however, as their wooden clogs are sound they do not care. The pavement is laid with a gutter in the centre leading to the sewer. The structure is not bad, but the practice, the absence of method, is most reprehensible. Also it is absolutely wrong that meat should hang, if even for only a short time, in close proximity to so much filth. The accompanying illustration shows wooden frames with large pegs on which the carcasses of sheep or quarters of beef can be hung immediately above the dung, blood, and offal that stagnate on the pavement.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

An Institute for Deaf-Mutes.

THERE are in Birmingham about 700 deaf-mutes, the majority of whom belong to the Birmingham and Midland Adult Deaf and Dumb Association, and although, as a rule, scarcely more than a fourth of the whole number can attend any given social meeting, still the accommodation possessed by the association is quite inadequate. This being the case, an attempt is shortly to be made to secure funds for the purpose of acquiring a central institute of sufficient size. It is estimated that about £5000 will be required. The scheme

should meet with success, as the people for whose benefit it is intended are for the most part thrifty, energetic, and deserving, but their affliction prevents them obtaining high wages. They are therefore thoroughly deserving of help, and the help may be given the more freely to these people inasmuch as there does not seem to be any marked tendency towards the transmission of the affliction from parents to children, consequently benevolence in this direction will not help to perpetuate degeneracy.

Scarlet Fever and Diphtheria.

In spite of a slight recrudescence during the past week we seem now distinctly to have passed the summits of the mild epidemics of scarlet fever and diphtheria which have simultaneously held sway in the city. Both epidemics commenced in September. On the 29th of that month there were 271 scarlet fever and 49 diphtheria patients in the hospital. By the middle of November the number of the former had risen to 382 and of the latter to 103, and on Saturday last the scarlet fever patients had been reduced to 318 and the diphtheria patients to 101. No doubt fluctuations may yet occur but it is scarcely probable that there will be any steady increase during the next few months. Luckily both epidemics have been very mild and the deaths extremely few. It is to be hoped that the after-effects will be few but that we shall never know, for it is not possible at present to obtain trustworthy statistics of the sequelæ.

"Seasonable" Weather and the Death-rate.

The after-effects of the severe weather at Christmas have shown themselves, and our death-rate rose first to 18.3 and then, during the past week, to 22.0 per 1000. The increase is due almost entirely to deaths from respiratory diseases which rose from 39 to 61. It is doubtful if a green Christmas time, in spite of the traditional fat churchyard associated with it, would produce so striking an increase in the death-rate, and many of us who are past the enjoyments of snow and frost will hope that it may be long before such another "seasonable" Christmas is recorded, for discomfort and death are its handmaids.

Christmas and New Year in the Hospitals.

The Christmas and New Year festivities are now completely over. The former were enjoyed in so-called seasonable and the latter in unseasonable, but more comfortable, weather. Whether the weather had anything to do with it or not there was a snap and go about the Christmas merry-making which was more or less lacking at the New Year. Our hospital staffs give much thought and work to make everything look and go well and as a result all the hospital wards were cheerful and some were quite artistically decorated. The visit of Father Christmas, who is still an institution in some hospitals, and the distribution of his gifts, proved, as usual, sources of great delight, especially to the children.

JAN 8th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Physical Degeneration: Liverpool's Problem.

RECENT disclosures would warrant the conclusion that the strength and virility of the class which has supplied the bone and sinew in the past are decaying because many of its children are emaciated and stunted in growth owing to a deficiency of food. The grave importance of the situation has been recognised by the legislature in the recent Act of Parliament passed for the feeding of underfed children. The paper read on Jan. 5th before the North of England educational conference at Bradford by Mr. A. S. Arkle of Liverpool on the subject of physical degeneration is deeply interesting, and showed the need of a substantial application of the benefits of the measure. At the time of the sittings of the Committee on Physical Deterioration Mr. Arkle, at the request of the Liverpool education committee, carried out a series of investigations in three typical council schools in Liverpool, "rightly judging that true knowledge of any existing evil is the first essential step towards remedying it." His observations extended over a period of 12 months. He minutely examined all the children in these three schools, taking their height, weight, chest measurement and expansion, condition of eyes, nose, and throat, and noting their nutrition, intelligence, and clothing. For comparative purposes he also examined all the boys in

the principal secondary schools in Liverpool and Birkenhead. The conclusions arrived at as a result of these investigations were as follows:—

(c) That the difference of physique between the children in the secondary schools and the poorer council schools has reached an alarming proportion; (b) that this deterioration appears to grow greater as life progresses; (c) that, medically, there is nothing to account for the deterioration; and (d) that the industrial school figures show that by care and attention this deterioration can be stopped and to some extent, at any rate, the leeway made good.

The total number of children whom Mr. Arkle examined was 2477—from secondary schools, 366; from elementary schools, 2111. The results obtained were nearly identical in all the secondary schools and to make the average yield a fair test, when compared with other schools, a large group of boys in this class had to be taken. In the matter of height he found the average, at seven years of age, of boys in the secondary schools, to be 3 feet 11·8 inches, as compared with 3 feet 9·3 inches in the best class of elementary schools; whereas in the worst class of the latter the average height was only 3 feet 8 inches. At 11 years of age the average height of boys in the secondary schools was 4 feet 7·5 inches, as compared with 4 feet 1·7 inches in the lowest class of elementary schools. At 14 years of age 5 feet 1·75 inches was the average height in the secondary schools, as compared with 4 feet 7·25 inches in the lowest class of elementary schools. The weights of the boys in the different classes of schools were equally remarkable, showing at 14 years of age an average difference in weight of 1 stone 9·25 pounds in favour of the boy at the secondary school. Mr. Arkle concludes his paper by saying that the results of his investigations (a portion of which are condensed here) force him to the conclusion that degeneration has reached an alarming stage. He asks, Of what use is it to educate children whose minds and bodies are absolutely unable to benefit thereby?

Sir Robert William Boyce, F.R.S.

Professor Sir Robert W. Boyce, the dean of the School of Tropical Medicine, who has been in ill-health for some months, was a passenger on board the R.M.S. *Karina* which sailed from the landing stage on Jan. 5th for Madeira. Sir Robert Boyce was accompanied by Dr. G. Boyce and a nurse. A large number of friends arrived at the landing stage to wish him *bon voyage* and a general hope was expressed that he would return to Liverpool and to his duties at the Thompson Yates laboratories restored to his usual health. Sir R. Boyce, though still feeble, appeared to his friends to be gaining in strength.

Liverpool Infirmary for Children.

Her Royal Highness the Duchess of Albany will open the new infirmary for children on Thursday, Jan. 10th. Her Royal Highness, who will be the guest of the Earl and Countess of Derby, will be received at the new infirmary by the Lord Mayor and Lady Mayoress, the president of the infirmary, the chairman of the building committee, the honorary treasurer and honorary secretary, and the lady members holding official positions. The Lord Mayor will preside at the opening ceremony and the president of the hospital will ask Her Royal Highness to declare the building open and to receive presents from children. A vote of thanks to Her Royal Highness will be moved by the Earl of Derby and seconded by the Lord Bishop of the diocese.

The Cost of a Snowfall in Liverpool.

The health committee expressed much pleasure at its meeting on Jan. 3rd on the expedition with which the snow had been cleared from the streets after the fall on Dec. 30th. The cost was £2500, of which £1075 were paid to unemployed labourers at the rate of 4s. per man a day. In the neighbouring borough of Bootle the call for labour to clear away the snow was not responded to, causing much delay in removal and inconvenience to traffic generally.

Jan. 5th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Pauperism in Wales.

It appears from the recently issued return of the Local Government Board that the number of paupers relieved on July 1st, 1906 in the whole of England and Wales, including London, was equal to 25 per 1000 of the estimated population and to 28·5 per 1000 in London alone. Judged by the same standard there was considerably less pauperism in the

southern counties of Wales than in the northern. In the six southern counties the proportion of pauperism to population varied from 16·9 per 1000 in Radnor to 26·3 per 1000 in Cardigan and in the six northern counties from 23·3 per 1000 in Denbigh to 33·4 per 1000 in Anglesey. The proportion in this last county is the highest in the whole of England and Wales, the next being Merioneth with 29·4 per 1000. It is very doubtful whether these figures really indicate a greater amount of poverty in the northern part of the principality or merely point to greater laxity in the administration of the Poor-laws.

Inferior Milk in Cardiff.

A dairyman was summoned in Cardiff on Jan. 3rd for selling milk adulterated with boric acid to the committee of the Cardiff Infirmary. The defendant is under contract with the committee of that institution for the supply of milk. Evidence showed that the milk had 45 per cent. of added water, was deficient in fat to the extent of 10 per cent., and was adulterated by the addition of 0·046 per cent. of boric acid. The defendant was fined £10 and costs, the magistrates accepting the theory that the adulteration was accidental.

Pollution of the Avon at Bath.

At the last meeting of the Somerset county council it was decided to take proceedings against the corporation of Bath under the Rivers Pollution Prevention Act, 1876. The corporation does not admit that pollution of the river Avon takes place within the city boundaries. A scheme for providing sewage outfall works was considered some years ago, but the very great cost of the undertaking was apparently prohibitive and less costly proposals have not been sufficiently comprehensive.

Diphtheria in Chipping Sodbury.

In the autumn of last year a more or less circumscribed outbreak of diphtheria occurred in the rural district of Chipping Sodbury in Gloucestershire. There were altogether 35 cases, nearly half of which were in the parish of Frenchay. In a report which Dr. Francis T. Bond has presented to the district council he says that in treating such an outbreak the general impression seems to be that the proper course is to send the patients to the isolation hospital for treatment. Although cases of an exceptional character may with advantage be treated in an isolation hospital, he deprecates the crowding of the wards with every case that occurs, a course which would neither be in the interests of the patients nor economical for the ratepayers. There is abundant evidence, he says, that if antitoxin is administered promptly and in sufficient doses the risk of a fatal termination to a case is reduced to a minimum. In his opinion, when a medical practitioner considered that he had sufficient evidence to notify a case to the sanitary authority, it was the duty of such practitioner at once to administer antitoxin and thus to render it unnecessary to send the patient to the hospital.

Bridgwater Rural District Isolation Hospital.

Sanitary authorities have from time to time resorted to various expedients in order to lessen the obligations cast upon them by the Public Health Acts, but surely none is more ingenious than that which has been proposed to the Bridgwater (Somerset) rural district council. A committee of the council was appointed to consider the question of providing an isolation hospital and the council has now adopted the recommendation of the committee that every year a sub-committee should be appointed to assist the inspector of nuisances in seeking for a suitable building in which to accommodate infectious diseases whenever such is required.

The St. Columb Board of Guardians and Vaccination.

At a meeting of the St. Columb (Cornwall) board of guardians held on Jan. 3rd the vaccination committee reported that after examining the books of the public vaccinators it was of opinion that the charges brought against a public vaccinator by the Local Government Board inspector could not be substantiated, as it could find no evidence of postponement certificates being granted for trivial reasons, and in all cases of postponement he afterwards, with the exception of his own child, had vaccinated every child. The guardians unanimously adopted the report, and decided to send a copy of the correspondence with the Local Government Board to Mr. McArthur, M.P. The matter has been already reported in THE LANCET, and it will be remembered that the Local Government Board refused to sanction the appointment of the public vaccinator in question, whilst the guardians would not rescind his appointment by them.

Jan. 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Year's Work of the Edinburgh Royal Infirmary.

A MEETING of the general court of contributors of the Edinburgh Royal Infirmary was held on Jan. 7th. The annual report shows that the number of patients treated in the wards was 11,216; of these, 820 died, while of this number, 192 died within 48 hours of admission. In the out-patient department 37,235 patients have been treated. The total ordinary income for the year was £33,695, being slightly less than the sum received in the previous year. Hospital tickets showed an increase of £226. The ordinary expenditure amounted to £52,116, being £1972 more than in the previous year. The increased expenditure is accounted for by an increase of 11 in the number of occupied beds, the increased cost of the new surgical out-patient department, the introduction of massage treatment, the perfecting of the telephonic system, the increasing cost of the electrical department, and the increased demand for modern appliances both in the medical and surgical departments. The report mentions a number of improvements and additions made to various special departments which have added to their efficiency. The expenditure, while it has increased, shows that great reductions and economies have been effected within the past few years, notably in fuel. Under the head of wines, spirits, gluten, bread, and meat extracts there has been a reduction from £736 to £299; in the detail of beeswax and turpentine for polishing the floors there has been a saving of £1501. In referring to the annual report in the past few years reference has been made to the valuable work which Colonel Warburton, the present superintendent, has done in effecting great economies in the working of the infirmary without in any way reducing its efficiency and there is no doubt that his administrative ability is still effective. The legacies and donations of £100 and upwards amounted to £22,670. The extraordinary expenditure amounted to £14,352, including sums for drainage, reconstruction of operating theatres, new surgical out-patient theatre and reconstruction of the department, electric lighting improvements, &c. The new surgical out-patient department, which has made a charge of about £700 a year upon the funds, is regarded as justifying the initial outlay and the annual expense. The reconstruction of the incidental delirium department and of the medical out-patient department has been delayed owing to the urgency of other works requiring to be completed. The report ends with an appeal for more funds and the expression of the hope that the managers will not be compelled to encroach upon their reserve funds.

Complimentary Dinner to Dr. Norman Walker.

The Fifeshire Medical Association, of which society Dr. Norman Walker was recently president, entertained him at dinner in Kirkcaldy on Dec. 28th, 1906, on the occasion of his election as Direct Representative for Scotland on the General Medical Council. Mr. R. Balfour Graham of Leven, the present president of the society, proposed the toast of the evening, which was suitably replied to by Dr. Walker.

The Scottish Poor-Law Medical Officers' Association.

The report of this association has just been published. It shows that the action of the association in behalf of its members in respect of the autocratic decisions of parish councils has been most valuable, and has also received considerable endorsement from the Local Government Board. An increasing number of Scottish Members of Parliament are manifesting interest in the present highly unsatisfactory position of the Poor-law medical officers of Scotland.

Reconstruction of Glasgow Royal Infirmary.

The work of reconstructing the Glasgow Royal Infirmary on the plans sanctioned by the directors has made considerable progress during the past year and some idea can now be had of the form which the institution will take when finally completed. The new structure, speaking generally, consists of three blocks. To meet the necessity of carrying on the infirmary with unimpaired efficiency while the new buildings are in process of erection it was resolved to proceed first with the northern block, which will occupy a site on what was formerly vacant ground lying between the present northern surgical block and St. Mungo's College. The first turf was cut on May 25th, 1905, and already

the building has been carried to the height of the first of the five storeys of which it will consist. To make way for the new gateway block which will be erected a little to the north of the present entry to the wards, the old gateway block has been demolished, and the work of excavation and laying the foundations for the northern portion will be begun very shortly. In this block there will be a waiting-hall for patients and their friends, examination rooms, and two small operating theatres. The other half of the block, which cannot be undertaken in the meantime, will contain the casualty wards. The entire scheme when finished will give accommodation for 680, as compared with 584 patients in the present institution. In the northern block, with the erection of which a beginning has been made, there will be accommodation for 250 patients, and so soon as it is finished it will be occupied, the patients being transferred from one of the sections of the old building, and further work of reconstruction will be commenced. No decision has yet been arrived at as to which of the remaining blocks will be built first. The directors have, however, in contemplation an immediate extension of the nurses' home to be erected to the eastward of the present building. A new power-house and laundry are also to be erected in connexion with the scheme of reconstruction.

Appointments to Glasgow Royal Infirmary.

At a meeting of the managers of Glasgow Royal Infirmary held last week the following appointments were made: Visiting physician, J. B. McKenzie Anderson, M.B., O.M. Glasg.; anaesthetist, J. King Patrik, M.B., Ch.B. Glasg.; and extra assistant bacteriologist, Miss Lizzie Fraser, M.D. Glasg.

Glasgow Corporation and Sweated Labour.

A special committee has been appointed by the town council of Glasgow to consider the question of "sweated labour" among women and children as it exists in the city of Glasgow. The scope of the inquiry is to be as follows—viz., to hear evidence from the medical officer of health, the sanitary inspector, the Scottish Council for Women's Trades, the Glasgow Trades' Council, the Scottish Christian Social Union, and other bodies interested in labour questions as to their knowledge of sweating among women and children; employers and employees as to the conditions, hours, and wages of women and children in regard to work performed for factories and workshops by inside and outside workers; and workers who do work at home solely on their own account.

Jan. 8th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Prevention of Tuberculosis in Dublin.

A GREAT deal has been spoken and written about this important matter but not very much has been really done. Sir Charles A. Cameron, medical officer of health of the city, recently addressed a letter to the press from the municipal buildings in connexion with the work recently performed by the disinfecting department as regards pulmonary consumption. The letter shows that the deaths caused by pulmonary consumption in 1906 numbered 937 and were fewer by 30 than in 1905. Of these deaths 182 occurred in the Hospice for the Sick and Dying, the Incurables Hospital, and lunatic asylums; 66 in the general hospitals; 140 in the North Dublin union; and 128 in the South Dublin union, making a total of 516 in public institutions, or more than half the total deaths from consumption. Sir Charles Cameron says that the Registrar-General sent every week a list of the deaths from consumption which enabled disinfection of the rooms occupied by the deceased to be carried out. 258 dwellings were disinfected after deaths from consumption. Only 12 of these deaths were notified by medical men, all of whom were dispensary physicians. 24 dwellings were disinfected on notification from physicians that the patients had been removed from them, and 30 dwellings were disinfected on notification from the union authorities that consumptives had been admitted to the union from these dwellings. In 23 instances incorrect addresses of the deceased were given. Of the 421 deaths that occurred outside public institutions the premises occupied by the deceased were disinfected in 312 instances.

The letter is, and was, of course, intended to be, a forcible argument in favour of a system of compulsory notification of pulmonary tuberculosis.

Royal College of Surgeons in Ireland.

The annual college dinner will take place on Jan. 26th. His Excellency the Lord Lieutenant has graciously signified his intention to be present. A meeting of the College will be held before the dinner for the purpose of conferring the Honorary Fellowship on Mr. Priestley Smith, professor of ophthalmology in the University of Birmingham.

The Health of Belfast.

In moving the adoption of the minutes of the public health committee at the meeting of the Belfast corporation on Jan. 1st the chairman (Dr. J. King Kerr) questioned the estimates of the population of Belfast made by the Registrar-General and stated that in his opinion "the death-rate for the last two years has been over-estimated as contrasted with the under-estimate prior to 1901." He thought that the facts showed that the statistics were absolutely untrustworthy referring to the last 12 years, with the exception of one year, adding that "Belfast had one of the lowest death-rates on record." It would have been wiser to allow the statistics of the year that has just closed to be put before the public by the recognised official authority, the Registrar-General, because the means employed hitherto by the health authorities of Belfast to collect any statistical information, apart from that supplied to them by the Registrar-General, have not been remarkably wise. To say that "Belfast had one of the lowest death-rates on record" when the medical officer of health, at the same meeting at which this statement was made, reported the death-rate as being 18.1 per 1000 was over-bold. A point in favour of the existing health administration of the city was made "that typhoid as an endemic disease was gradually dying out in our midst," but the official methods of trying to combat the late milk typhoid epidemic were not quoted. When attention was drawn by one of the council to the custom of milk-carts collecting refuse before returning to the dairies (any afternoon one can see carts of manure going out of Belfast with small empty butter-milk wooden vessels on them) the reply given was that the public health committee had no power to stop the revolting procedure. Possibly; but powers should have been acquired to prevent such a nuisance the moment it came to the official ears. The public health committee will have plenty of matters to explain at the coming commission on the health of the city.

A Nurse's Decoction.

At an inquest held in Belfast on Jan. 4th, in reference to the death of an infant, five days old, the nurse who had been in attendance said that she gave a quarter of a teaspoonful of the following mixture to the child owing to the infant having pains: a pennyworth of magnesia, a pennyworth of sweet manna, a pennyworth of sugar, a pennyworth of tincture of rhubarb, a pennyworth of essence of aniseed, and a half-pennyworth of laudanum. This she boiled for an hour and then gave the child a quarter of a teaspoonful. The jury found that the child had died from opium poisoning due to the nurse, through ignorance, administering an overdose of laudanum for the purpose of relieving pains.

Jan. 22.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Early Diagnosis of Tuberculous Disease.

At a meeting of the Academy of Medicine held on Dec. 18th, 1906, M. Barot read a paper in which he endeavoured to show that tuberculous disease might be diagnosed in an early stage of development, which he called *germination ganglionnaire* before there was any visceral infection. The paper was based upon 250 cases observed by M. Barot himself and the diagnostic signs on which he relied were four in number, deriving their value from simultaneous occurrence. They were loss of weight, scars in the morning, a painful sensation when pressure was made on the vertebra and the sternum, and an abnormal rough resonance of the lower register of the voice over the vertebra; there were, moreover, a number of auxiliary signs which served to confirm the diagnosis. M. Barot said that this early stage of tuberculosis was of very variable duration

and that during this period judicious dieting and treatment had an excellent effect. The investigation and recognition of this developmental stage were of great importance for the prevention of tuberculosis.

Old Age Pensions.

The fifth commission of the municipal council of Paris has fixed at 30 francs the amount of the monthly sum payable from the commencement of 1907 to aged persons who benefit by the Pensions Act (*la loi sur l'assistance obligatoire*). This decision remains to be confirmed by the council which at the same time will have to provide the requisite funds. The general council of the department of the Seine will also have to consider the whole question in connexion with the confirmation of recommendations of a similar nature made by the communes of the department.

Pseudo-Hermaphroditism due to Hypospadias.

At a meeting of the Surgical Society held on Dec. 19th, 1906, M. Porzi communicated an observation made by Dr. Barnsby on a male child who had up to the age of 12 years been regarded as a girl. The child's fondness for the society of girls and various traits of character led the parents to have him thoroughly examined by Dr. Barnsby who found that the case was one of hypospadias and that there was a testicle in one of the supposed labia majora. To remedy this abnormality Dr. Barnsby performed an operation in several stages. He first straightened the penis by dividing a band, then formed the distal extremity of a penile urethra, and joined it to the existing urethral orifice by flaps which also closed the hypospadias aperture. The result was excellent.

Bequest to the Pasteur Institute.

M. Audrao, a recently deceased landowner in the department of the Eastern Pyrenees, has bequeathed to the Pasteur Institute his whole fortune, which is estimated at more than 1,000,000 francs. The notary of Luc, the town in which the testator resided, has come to Paris to see Dr. Roux and to inform him of the facts. Some time must elapse before the Pasteur Institute will know whether it is the sole heir, as the will conveying the bequest is of old date and there is a possibility that the deceased may have made a later one which still remains to be found.

Jan. 7th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Sleeping Sickness.

Professor Robert Koch, who some time ago made his third visit to Africa, has sent a report of his investigations on the subject of sleeping sickness to the Imperial Health Office and this report has been published in the *Deutsche Medizinische Wochenschrift*. He first proceeded to the district of Muansa in German East Africa, but found that, although *Glossina palpalis*, the insect which conveys the parasite, was prevalent, there were no cases of the disease at that place. Professor Koch was therefore very gratified when the British commissioner of Uganda, Mr. Hesketh-Bell, invited him to stay in one of the Sese islands and to make use of the laboratory at Entebbe. He was told by the missionaries that the epidemic had been so disastrous for the inhabitants of the island that their numbers had fallen from 30,000 to 12,000 within four years. There were, however, very few patients in the hospital, because the natives did not bring sick persons for treatment, believing that medical science was unable to give relief. Professor Koch first examined the blood of the patients, but in 180 cases the trypanosoma was discovered only three times. As this result was very unsatisfactory and in contradiction with the clinical symptoms the next step was to examine the lymphatic glands of the neck, which are always swollen in this disease. According to the statements of the English medical men, Dr. Gray and Dr. Graef, the trypanosoma was discovered in 160 cases out of 163. As from 60 to 70 per cent. of the population have swollen glands and as of the remainder a great number have certainly contracted the disease, prophylactic measures were of no use but the desideratum was to destroy the trypanosoma within the patient's body. An arsenical compound known as atoxyl (meta-arsenic anilide) was especially tried. Subcutaneous injections of 0.5 gramme made on two successive days did not produce any toxic effect and puncture of

the glands showed that the trypanosomata had disappeared. In some cases the parasites reappeared after about ten days but these were exceptional. In serious attacks the treatment had to be repeated after ten days and in slight cases after 15 or 20 days. No undesirable symptoms were observed even when the injections were made for the third or fourth time. Puncture of the glands showed that trypanosomata were still present six hours after the injection but that they totally disappeared after eight hours; at the same time the general state of the patients improved. The news of the success of the treatment soon became widely spread by the patients themselves among the population and crowds of natives therefore came from the islands and from the mainland in the hope of obtaining benefit. On some days about 800 persons presented themselves with this object. Owing to the relatively small available quantity of the remedy only a minority of the patients—namely, 359, of whom 80 were severe cases, were selected. In his last report, dated Nov. 5th, 1906, Professor Koch states that he has become persuaded that atoxyl is as certain a remedy against sleeping sickness as quinine is against malaria. He had meanwhile employed the treatment for 800 severe cases and the patients improved so much that it might be stopped after two or three months. The patients must then be kept under observation for the same period in order to ascertain whether relapses occur or not.

Cancer of the Appendix.

At a recent meeting of the Berlin Medical Society Dr. Theodor Landau spoke on the subject of primary cancer of the appendix. He said that up to the present time only 58 cases of this condition have been described in medical literature and that in the majority of cases it had been found accidentally. In about 60 per cent. of the cases the growth was situated at the apex of the appendix and the surrounding tissue showed an inflammatory reaction. In two instances the growth had perforated through the abdominal walls, forming a fistula, but a perforation into the abdominal cavity had never occurred, neither were metastases frequent. The clinical symptoms were those of appendicitis, except that the pain, instead of being dull as in appendicitis, was cutting and lancinating, and was especially severe at night. Relapses very seldom happened after the removal of the appendix. The cases were, as a rule, believed to be appendicitis and it was only in the course of the operation and afterwards by microscopical examination that the nature of the growth was ascertained. In a case where he had performed a laparotomy for myoma he removed the appendix because it was found to be swollen. Subsequent microscopical examination proved that it was affected with cancer. In every laparotomy for whatever cause the appendix should be the object of careful examination.

Honour to Professor von Bergmann.

The seventieth anniversary of the birthday of Professor von Bergmann was made the occasion of various celebrations by the medical profession of Berlin and elsewhere, showing the esteem in which he is held by his professional brethren and his numerous patients. On Dec. 18th, 1906, a banquet took place at which were present Professor von Bergmann himself, some members of his family, his present and former assistants, many civilian medical men, and officers of the Army Medical Corps. Professor Heubner, the dean of the Berlin Medical Faculty, proposed the health of Professor von Bergmann, and Professor von Augerer of Munich proposed the health of his family. Professor von Bergmann, in his reply, said that he was a young man far from having a special inclination to the study of medicine; to the great amusement of the assembly he told them that his original intention was to become a clergyman but as by a decree of the Emperor Nicolas (Professor von Bergmann is a Russian by birth) the total number of ecclesiastical students could not exceed certain limits, he was refused matriculation in the faculty of theology and therefore became a medical student. He declined to be compared with geniuses like the late Professor Billroth or Lord Lister but said that he was always favoured by circumstances, as in the choice of his career. Professor von Bergmann, who is president of the Berlin Medical Society, was made honorary president on the occasion of his birthday. It is reported that he will soon retire from his post and that Professor von Eiselsberg of Vienna will not improbably become his successor.

Serotherapy.

THE new year opens with an important adjunct to Italy's resources—the new Sero-Therapeutic Institute at Milan. The inaugural ceremony, which attracted a numerous audience of the profession and the lay public, was conducted by the Senator Luigi Mangiagalli of the "Istituto Lombardo di Scienze e Lettere," who, in a rapid and vivid sketch, recalled the first inception of the institute in 1894, its excellent work in spite of adverse vicissitudes, financial and other, and finally, its development into the enlarged and virtually new institute just entering, under happy auspices, on its beneficent career, curative, hygienic, and scientific. In the stately and fully equipped edifice in which it is now accommodated the staff of the institute may reasonably be expected to improve on its record, honourable as that record has been for its great and successful experiments in the immunisation of oxen with the bovo-vaccine of Behring and also for the educative function which it has discharged in the initiation and equipment of similar institutes throughout Italy which have, in turn, become centres of post-graduate study. Professor Belfanti supplemented the Senator Mangiagalli's discourse with a history of the scientific discoveries to which the institute owed its origin, dwelling on the importance of the "Infinitely little" in biology and medicine and citing the names of Davaine, of Pasteur, and of the less known but hardly less epoch-marking Cornalia whose discovery of the organic nature of the active cause of the silkworm disease paved the way for other workers in the same field. Coming to the productive output of the institute, he showed that it supplied 20,000 *bocette* (tubes) of antidiphtheritic serum and, saved 6600 infantile patients a year, to say nothing of other preparations directed against other maladies. Besides curative serums it provided protective or prophylactic serums, such, for example, as the "serum anticarbunculosum" (a preparation which previously had to be imported into Italy from France), with the result that the home-made Italian serum has been effectively applied to 800,000 cattle. In small-pox the work of the institute had been not less signal, destined as it now is to become the chief source of supply of the "vaccino Jenneriano" throughout Italy. In every department indeed of sero-therapy the institute promises rapid and extensive improvement in the beneficent work which it has already achieved and in its rehabilitated and completely equipped development constitutes—to the honour of Milan—a noble "New Year's gift" to the nation.

Arturo Calvo.

At the early age of 29 years this accomplished physician has fallen a victim to professional duty in the Florentine Clinique, of which he was an able and highly esteemed member. His university career was a distinguished one and after having won the coveted "Tacchini prize" he proceeded for post-graduate "perfezionamento" to Germany and thence to Paris, making, during his two years' sojourn special studies in the physiology and pathology of the stomach. His conclusions have been embodied in a publication already popular in the profession, though but the prelude to further work in the same important field. Having contracted typhoid fever at his post he finally succumbed to the disease in spite of the skill and care of his colleagues who, I understand, are preparing a permanent memorial of him in the clinique which he served so well.

The Darwin Centenary.

Though still about two years off, the hundredth anniversary of the birth of the author of the "Origin of Species" (Feb. 12th, 1809) has already evoked the commemorative enthusiasm of his admirers—and their name is legion—in all the Italian seats of learning. The recent death of Brancati whose work on the "Bankruptcy of Science" impressed the continent so vividly, followed by the tributes to his able if ineffectual advocacy of a declining cause, has prompted Dr. Mario Cermenati, professor of the history of the natural sciences in the University of Rome, to a stirring vindication of the great exponent of evolution. Highly successful before its academic audience, it is now, in its printed form, being widely read by the general public as the prelude to a tribute, organised on a national scale, to the memory of the great

English philosopher. It is proposed in some quarters to celebrate coincidentally with that of Darwin's birth the centenary of the publication of Lamarck's "Philosophie Zoologique," by many considered as an anticipation, however indecisive, of the "Origin of Species." This, however, by the way. Italy is sure to have the support, in continental Europe, of other nationalities besides those of Latin lineage with whom the doctrine of evolution has had from the first a peculiarly hospitable reception.

Overcrowding and Infantile Mortality.

IN a paper read at a recent meeting of the Medical Society Dr. Pach called the attention of the medical profession and of the Government to the importance of prophylactic measures especially in the protection of children from the evils of overcrowding. He selected Budapest as a field for his researches because it was a large city undergoing rapid and continuous increase and the subjects which he took for investigation were, on the one hand, the influence of modern conditions of life upon the development of diseases and the death-rate, and, on the other hand, the general hygiene of modern dwellings and occupations. He found that from the year 1874 until 1900 the mortality of infants and children up to the age of five years had steadily increased from 26·7 to 29·9 per cent., and if the figures for the different districts of the city were tabulated separately a very close relation between overcrowding of dwelling houses and the mortality of children was brought out. For instance, in the factory districts of the city from seven to 11 persons occupied a lodging which consisted of from one to three rooms, whereas in the other districts of the city from two to five persons occupied a lodging which consisted of from two to five rooms. The factory districts showed an annual general mortality exceeding 25 per 1000 and an infantile mortality exceeding 120 per 1000, while for the city the general mortality was 21 per 1000 and the infantile mortality was 95 per 1000. When station in life was taken as a basis of computation it was found that against 285 children of the well-to-do classes 4780 children of the poorer class died in the year 1904 and of these 270 succumbed to pulmonary tuberculosis. In the same year 2920 persons died from pulmonary tuberculosis, of whom 85 per cent. were poor and only eight (i.e., 0·27 per cent.) were well-to-do. More than 48 per cent. of these deaths occurred in rooms on the ground floor or below the level of the street. This showed that the primary requisite for the prevention of tuberculosis was not the erection of sanatoriums and hospitals but the better housing of the poor. The motto of the reformer ought to be "houses for the healthy" rather than "hospitals for the sick." In the interest of the public health there was an urgent necessity for the demolition of insanitary buildings and slums, the prevention of overcrowding, the erection of working-class dwellings, the improvement of the building regulations, the prohibition of the modern system of overbuilding on insufficient areas, the enactment of regulations fixing the maximum number of occupants for each house or part of a house, and the prohibition of subletting. What was wanted was, in fact, more light and more air.

A Dermoid Tumour of the Scrotum

Dr. Porges recently had an opportunity of showing a very rare example of dermoid tumour which on account of its position had several times been mistaken for some other disease. The patient was 22 years of age. Inspection showed that the scrotum contained three swellings, the upper two of which were easily recognised as the slightly enlarged testes, whilst the lower tumour was quite isolated. When the reflex of the testes was elicited the lower tumour did not move, thus proving that its origin was not situated within the testicles or their sheaths; the diagnosis of hydrocele or spermatocele could therefore be excluded. The size of the tumour was about equal to that of a man's fist; it reached to the perineum; the integuments were normal, easily folding. The scrotal raphe was situated exactly in the middle of the soft elastic tumour. A puncture showed the presence of an oily fluid. A diagnosis of dermoid cyst of the scrotum was made and was afterwards proved by operation to be correct.

The Consumption of Tobacco in Austria.

Statistics compiled by the Government departments show that the consumption of tobacco in Austria is slowly decreasing. Cigarettes are on the whole more favoured than formerly and have to some extent displaced cigars and pipes. Neurologists find in this an explanation of the increase of neurasthenia amongst both young men and men of advanced age, as the sale of cigarettes and cigarette tobacco has increased by 15 per cent. in one year. As regards the quality of the tobacco, the better sorts are in most request, showing that the nation, or at least the smoking part of the nation, is comparatively affluent. The total amount of 36,945 tons of tobacco works out at a yearly consumption of 1·33 kilogrammes (equal to three pounds) per head of the population. Austria stands in this respect fifth on the list of tobacco smoking countries. Experiments made with a view to reduce the percentage of nicotine contained in tobacco have resulted in the production of two types of cigarettes called "nicotine-free" which, however, in reality are only "nicotine-poor." By treating the tobacco leaves with a 1 per cent. solution of caustic potash and afterwards washing them well about 50 or 60 per cent. of the nicotine is extracted so that the alarming symptoms of nicotine poisoning are less likely to arise. When, however, 30 or 40 of these new cigarettes are smoked in a day there is no difficulty in recognising that they are not quite free from the poison.

Paying Hospitals in Vienna.

The grievances of the medical profession, which are already ample and well founded, are to be increased by a new scheme of the Government which is contemplating the erection of paying wards or rather the addition of such wards to the existing accommodation in the general hospitals. These new wards are to be available for such classes of the population as cannot afford to pay for beds in expensive private sanatoriums but are unsuitable cases for the public hospitals under present conditions. It is expected that for a payment of 10 kronen (about 8s.) a day patients may obtain in these wards a room with one bed and for 6 kronen (5s.) a day accommodation in a room with from two to four beds. But the directors of the hospital wards are to be the visiting and consulting physicians, whilst the patients will be under the immediate care of the resident hospital staff. This latter restriction, which practically excludes the general practitioner from continuing to treat his patient, is naturally condemned by the greatest part of the profession. In spite of the protests that have been made and in spite of the opinions expressed by various hospital physicians the new scheme is being hastened forward by the Government with a view to increase the funds of the general hospitals, which have become rather depleted.

Medical Lectures in English.

As the number of English-speaking medical men (mostly Americans) at the University of Vienna is upwards of 100 several professors and *privat-docenten* have decided to deliver a series of lectures in English, so as to enable the foreign medical men to take part in these courses if they find difficulty in understanding German. The fees for such courses amount to about £4 4s., or at the most to £8 8s., and the number of the students is as a rule restricted, especially in the classes of gynecology and surgery. There is at present no special English Association in Vienna but a branch of the American Medical Association has been established and conducts a number of courses which may be taken by any English-speaking medical man.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Matters of Hygiene in Public Schools.

THE Ministry of Public Instruction has taken energetic measures to improve the hygienic and sanitary conditions of all the Turkish public schools in the metropolis, which up to now were in a very unsatisfactory state. It was found, for instance, that many of these schools were never heated in winter, the children thus being exposed to cold and frequently suffering bitter consequences of such reckless treatment. The sanitary inspectors and some of the medical men of their respective districts seem to have

the glands showed that the trypanosomata had disappeared. In some cases the parasites reappeared after about ten days but these were exceptional. In serious attacks the treatment had to be repeated after ten days and in slight cases after 15 or 20 days. No undesirable symptoms were observed even when the injections were made for the third or fourth time. Puncture of the glands showed that trypanosomata were still present six hours after the injection but that they totally disappeared after eight hours; at the same time the general state of the patients improved. The news of the success of the treatment soon became widely spread by the patients themselves among the population and crowds of natives therefore came from the islands and from the mainland in the hope of obtaining benefit. On some days about 800 persons presented themselves with this object. Owing to the relatively small available quantity of the remedy only a minority of the patients—namely, 359, of whom 80 were severe cases, were selected. The Darwin Centenary.

Though still about two years off, the hundredth anniversary of the birth of the author of the "Origin of Species" (Feb. 12th, 1809) has already evoked the commemorative enthusiasm of his admirers—and their name is legion—in all the Italian seats of learning. The recent death of Brunetiere whose work on the "Bankruptcy of Science" impressed the continent so vividly, followed by the tributes to his able if ineffectual advocacy of a declining cause, has prompted Dr. Mario Cermenati, professor of the history of the natural sciences in the University of Rome, to a stirring vindication of the great exponent of evolution. Highly successful before its academic audience, it is now, in its printed form, being widely read by the general public as the prelude to a tribute, organised on a national scale, to the memory of the great

fresh-water swamps or other territory suspected of breeding malarial or other mosquitoes, at the request of any local board of health. The local boards of health are to be informed of the mosquito-breeding places shown on the maps of salt marsh areas and notice given to the owners to abate the nuisances and if the owners fail to comply the boards of health are to act. In all investigations under the provisions for the survey of fresh-water swamps, or other suspected territory stated, the report to be made shall state what mosquitoes were found, whether they are local breeders or migrants from other points, and, in case of migrants, their probable source, whether the territory in question is dangerous as a nuisance because of mosquito breeding, and the character of the work necessary to abate such nuisance and abolish the breeding places. Boards of health must then proceed to abolish the breeding places under their general powers and when necessary the State may assist the local authorities.

The Appointment of School Physicians.

The State of Massachusetts has passed a law providing a rigid medical supervision of the health of its school children. The school committee of every city and town in the Commonwealth is required to appoint one or more school physicians and assign one to each public school of the city or town with proper facilities for the performance of their duties. The physician is required to maintain a careful inspection of the school children, the teachers, janitors, and school buildings. Whenever a child shows symptoms of small-pox, scarlet fever, measles, diphtheria, chicken-pox, tuberculosis, tonsillitis, whooping-cough, mumps, scabies, or trachoma he shall be sent home immediately and the board of health shall be notified. Every child in the public schools shall be separately and carefully examined and tested, at least once in each school year, to ascertain whether he is suffering from defective sight or hearing or from any other disability or defect tending to prevent his receiving the full benefit of his school work, or requiring a modification of the school work in order to prevent injury to the child, or to secure the best educational results.

International Sanitary Arrangements of the American Republics.

The Third International Conference of American Republics, held at Rio de Janeiro during the last summer, adopted the following recommendations relating to international sanitation:—1. The adoption of the agreement of the delegates to the Washington Conference of 1905 in regard to uniformity of quarantine regulations against cholera and yellow fever. 2. The adoption of measures to obtain the sanitation of cities, and especially of the ports, and to attain, as far as possible, to a better knowledge and a greater observance of hygienic and sanitary principles. 3. That all American nations attend the conference of 1937 to be held at the city of Mexico for the purpose of securing some form of international agreement on such sanitation, it being suggested that there should be a committee in each country devoted to securing information and transmitting it through a central bureau at Montevideo to the International Sanitary Bureau at Washington. The action of the Rio de Janeiro conference marks a great advance over preceding conferences which related only to quarantine. This extension of the work of the conference is probably largely due to the communication of the surgeon-general of our public health service which was prepared at the suggestion of the Secretary of State and by him presented to the conference. This communication was a very able document showing the immense importance of international cooperation in general sanitation.

Jan. 12.

THE DIET OF TO-DAY.

THE question of the most suitable diet for the individual in health has been made the subject of numerous investigations in recent years. As to whether what is termed a full diet, containing a comparatively large amount of albuminous food or a diet including a much smaller quantity of such flesh-forming substances is better adapted for the conservation of physical and mental energy, the question is one upon which the opinions of scientific men are still a good deal divided. A lecture dealing with certain features of the diet problem was delivered by Professor W. D. Halliburton at the Incorporated Institute of Hygiene on Wednesday afternoon, Jan. 9th. The address was designed to be of a popular character and we are certain that the views of Professor Halliburton on some important phases of a matter that more directly concerns popular audiences than almost any that can be imagined will be read with interest. Professor Halliburton was on the side of the full diet, expressing the now unpopular view that it is safer to eat too much than too little. The experiments of Professor Chittenden of Yale University, although of first-rank importance, should be regarded, he thought, as by no means final. This well-known observer carried out a series of investigations in order to ascertain whether human beings did or did not eat a larger amount of albuminous food than was necessary and came to the conclusion that the intake of proteids by the flesh-eating races was far too great, and that the standard of 100 grammes daily set by Voit should be reduced to about half that amount. Professor Halliburton pointed out that while nitrogenous food is essential for the repair of tissue waste, the terms nitrogenous and nutritious must not be regarded as synonymous. Non-nitrogenous foods are equally necessary for the preservation of good health, as these supply energy and animal heat. Undoubtedly, a large amount of proteid food is not required for tissue repair, which means that its excretion causes waste of energy. It is, therefore, regrettable that most well-to-do persons eat more meat and drink more alcohol than is good for their health. Nevertheless, Professor Halliburton did not think it wise to accept Professor Chittenden's views in full, for the reason that the minimum diet is not necessarily the optimum. In support of this argument the lecturer gave as examples the dietary of the poor in large cities and the small amount of nitrogenous matter eaten by vegetarians; both classes, he considered, showed less resisting power to hardship and disease than those who were meat eaters, the beneficial effects of generous feeding in pulmonary tuberculosis, and of the rest cure and good feeding for various nervous diseases were here quoted in support of the lecturer's attitude. He was, he said, of the opinion that the amount of proteid food should not be limited to subserve the repair of waste tissue, for this means to live on the margin of danger; but he thought that experiments on a far wider scale than Professor Chittenden's must be carried out before dogmatic statements would be safe.

Dr. Loether, he reminded his hearers, has pointed out that in infants ten times the minimum quantity of nitrogen necessary for this purpose was provided by nature in their proper diet of milk, even allowing for growth. The real explanation of the usefulness of an apparent excess is that certain constituents of the proteid molecule are particularly essential for the building up of the tissues; the amount of those necessary constituents is very limited in the proteid molecule, and in order to obtain an adequate supply the body has to put up with a good deal of waste substance, but the large size of the liver appears to be an express provision of nature for dealing with this waste rapidly. The easy digestibility of the proteids of animal origin render them superior to those from the vegetable world and the so-called vegetarian has had perforce to recognise this by adding to his diet three of the richest products from the animal kingdom—viz., milk, cheese, and eggs. Vegetarianism in this sense would no doubt spread if the standard of cookery was raised, but bad cooking of vegetables rendered them more indigestible, whereas bad cooking of animal food did not possess this disadvantage so markedly. In reference to the Japanese the lecturer pointed out how sadly needed are accurate details of what this nation exactly does consume. There is no doubt that within

HOSPITAL SUNDAY IN PLYMOUTH AND BRISTOL.—The total amount received by the South Devon and East Cornwall Hospital as a result of Hospital Sunday, which was observed in Plymouth on Oct. 22nd, 1935, was £255. Jan. 27th is to be observed in Bristol as Hospital Sunday.

THE LATE DR. A. SHEEN.—At a meeting of the Cardiff board of guardians held on Dec. 29th, 1936, a letter was read from Mr. Bircham, the late Local Government Board Inspector for the District, placing on record his high appreciation of the services of the late Dr. Alfred Sheen. The guardians unanimously passed a vote of condolence with Dr. Sheen's family, the chairman alluding to the loss which the workhouse infirmary had sustained through his death.

neglected their duties of proper inspection, visiting the schools but very rarely and in a superficial manner. In spite, however, of such casual fulfilment of their obligations they never omitted to send in eloquent reports of their work and of the flourishing conditions of sanitary matters in the schools. Many of these schools are overcrowded, dark, damp, and with extremely foul lavatories. The Ministry of Public Instruction intends now to remedy matters in a most energetic manner. The guilty sanitary inspectors and medical men will be dismissed, more conscientious individuals appointed to occupy their place, and the school-buildings will receive the most careful attention.

New Regulations Concerning Imported Drugs.

Henceforward no drugs will be permitted to enter the Turkish Empire the composition of which is not known or the purity of which is below the required standard. If, however, these drugs are accompanied by certificates of some acknowledged official medical administration only indicating the elements of the composition, and if these certificates are submitted to the Custom House officials, the medicines will be allowed to be imported. Yet the certificates must be legalised by the Turkish consuls abroad. Altogether forbidden are drugs and compositions which contain such ingredients as cocaine, picrotoxin, anti-tuberculous serum of Koch, and cannabis indica (preparations containing hashish). Prohibited also are chemical substances which can be used for the manufacture of explosives, such as chlorate of potassium, chlorate of sodium, nitrate of potassium and sodium, the picrates, nitroglycerin, &c. These substances will always be confiscated as soon as they arrive at the Custom House.

The Rules of Moslem Conviviality.

In one of my previous letters I spoke of the rules laid down by Islam usage and precept as to how to behave appropriately and religiously at a dinner table. Here are some other interesting Mussulman injunctions of conviviality. The honour of being served first belongs to that of the invited guest who is in the possession of any high title or who has, in any way or sphere, distinguished himself. If the host himself is the oldest in the company or has any high decoration of merit he must first begin the meal without delay, in order not to let the others unduly wait. It shows bad up-bringing to be in a melancholy mood at table, or to speak of disagreeable things, or to engage in inappropriate discussions on matters of religious plety. Foremost of all, one must always be in good humour and talk of pleasant things, as did the Prophet himself. You must always help yourself from the side of the dish nearest to you and never try to find out the best bits, which ought to be left for other guests. If one of the invited has not much appetite you must ask him up to three times, with some kind chosen words, to partake of the meals. A longer insistence would cause *enmi* and would be most inappropriate. You must never stop eating before others, because in doing so you will embarrass them and cause them to finish quickly in imitation you. Never eat gluttonously but also never attempt to conceal your good appetite. Always eat little by little. Exaggerated compliments are always misplaced. The host's duty is to make his guests feel as comfortable as possible, encouraging the timid and shy. It is contrary to good taste to address and to fix the attention of a guest when he is eating. Even if the host is not accustomed to eat much he must always try not to finish before others. Should any dish be forbidden to him by his medical attendant he certainly must not partake of it but must, at the same time, excuse himself before his guests. It is absolutely necessary to avoid every movement or gesture which is apt to create disgust. One must, for instance, never tell anecdotes of a doubtful nature, never remove pieces from the mouth, and never sneeze without turning away one's head, never yawn, or clean the nose, or approach the head too near the dish. On quitting the table everyone should wash his hands, the most distinguished in the company first of all. Always wash them standing, never spit on the floor, and rinse well the mouth. It is good and pious work to invite friends to dinner, and especially people of the same religion. On the great day of judgment the time spent in good company with the necessary observation of the enumerated rules of conviviality will be accounted to one as a high merit. It is therefore advisable to eat slowly in order to prolong this time. Never go to a dinner party without being invited unless you are a very intimate friend of the host. In the last case it is even permissible to enjoy a dinner at a friend's house without his presence, as did very frequently the

Prophet himself and his disciples. A good Mussulman ought always to have a few ready dishes for some chance friends or people of his own religion. He must, however, never fall into debt and never entertain others at the expense of his own household. If you enter a house where feasting is going on never take part in it without being invited. If you happen to notice that the invitation extended to you is not sincere leave the house under some pretext or other as soon as possible, not, however, without having previously tasted some little bit. This is a sign of good up-bringing and shows the spirit of perfect courtesy.

Jan. 3rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Immigration Statistics for 1905-06.

THE United States Secretary of Commerce and Labor has submitted his report for the year ending June 30th, 1906. It appears that during that period there applied for admission to ports of the United States 1,178,785 aliens, 12,432 of whom were refused admission. This total represents an excess over the arrivals of the preceding year of 152,286. Three European countries contributed, approximately, 69 per cent. of the total—viz., Russia, 215,665; Austria-Hungary, 265,138; and Italy, 273,120. Notwithstanding the large numbers from Italy and Russia shown last year, the increase from those countries was 51,641 and 30,768 respectively. On the other hand, those countries the people of which are more nearly allied in race and social standards to the people of the United States have furnished fewer immigrants. Thus the number of immigrants applying for admission from Ireland decreased 17,950; England, 15,218; Sweden, 3281; Germany, 3010; Denmark, 1229; and Scotland, 1111. The Secretary suggests that if the number of aliens brought on any vessel were so limited as to bear a fixed ratio to the tonnage of each vessel, by making the ratio sufficiently large not only would there be an actual diminution in the total arrivals but many of the incidents of suffering and discomfort attendant upon steerage travel would be obviated.

War upon Preserved Candy under the Pure Food Law.

The Pennsylvania authorities have begun a war against "The Glucose Trust." The contention is that the sulphurous acid in the glucose, which is used principally in the manufacture of candies, is in sufficient quantities to make its use a violation of the food laws of that State. At least 500 small dealers in candies have been arrested in Pennsylvania charged with using the chemicalised glucose in their candies. The dealers appealed to the "Trust" for aid which was immediately granted, as they were the best customers of the company. The "Trust" paid all fines and immediately undertook to discover some adequate substitute for the sulphur dioxide. The loss to the company by these prosecutions is estimated to be \$500,000.

Railroad Casualties in the United States.

The Interstate Commerce Commission has published its annual report on railway casualties in the United States, from which it appears that 4225 persons were killed and 66,709 were injured. Of these numbers 418 passengers were killed and 11,185 injured, and 3807 employees were killed and 55,524 were injured. There is a great increase of injured in the last report over the preceding years, but the commission makes no statement as to the causes for the increase, whether it is due to growing business, efforts to attain greater speed, or increased carelessness of employees. The greatest number of deaths and injuries of passengers from a single cause is given in the tables as, "from falling from cars while getting on or off." The same statement is true of deaths and injuries of employees.

Abolishing Mosquito-breeding Areas.

The State of New Jersey, which has long suffered from the mosquito pest, has taken measures to exterminate the evil by radical legislation. The law recently enacted makes it the duty of the Director of the State Experimental Station to have all the salt marsh areas of the State surveyed and maps made indicating all of the mosquito-breeding places found on such areas, together with a memorandum of the method to be adopted in dealing with such places, and the probable cost of abolishing the same. Likewise, surveys and maps will be made of

Baltimore.—Dr. Alfred Buchwald, *privat-docent* of pharmacology and therapeutics in the University of Breslau, where he enjoyed the titular rank of professor.—Dr. Georg Reinbach, *privat-docent* of surgery in the University of Breslau.—Dr. Karl Schoenborn, professor of surgery in the University of Würzburg and formerly professor in Königsberg, aged 66 years.—Dr. Schnetzler of Carlsruhe, well known for his numerous exposures of quacks and quack medicines.—Dr. Pietro Celoni, *privat-docent* of pædiatry in the Florence Advanced Medical School.—Dr. Venneman, professor of ophthalmology in the University of Louvain.

Medical News.

THE annual dinner of the British Gynaecological Society will take place on Thursday, Jan. 17th, at the Café Monico. Amongst those who have accepted invitations to be present are the President of the Royal College of Physicians, the President of the Royal College of Surgeons, the Director-General of the Medical Department of the Royal Navy, and the President of the Obstetrical Society of London. Mr. F. Bowreman Jessett will preside, and it is hoped that there will be a large attendance of Fellows. Any who have not yet intimated their intention of being present, and who intend to do so, are requested to communicate with Dr. Beckett-Overy, 24, Alexander-square, South Kensington, as early as possible.

DONATIONS AND REQUESTS.—The treasurers of the Middlesex Hospital have received a donation of 1000 guineas from Mrs. Ralph Price to endow a bed in the female cancer wards in memory of her husband.—Mr. W. J. Tatem of Cardiff has given 1000 guineas to the Cardiff Infirmary for the endowment of a cot in memory of his deceased son, Master T. S. Tatem.

MEDICAL MAGISTRATES.—Dr. Lachlan Grant and Dr. R. R. Macculloch have been placed on the commission of the peace for Argyllshire.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

ALLEY, SAMUEL H., M.D. Balt., has been appointed Clinical Assistant to the Chelsea Hospital for Women.
COGHELL, E. F., M.R.C.S., L.R.C.P. Edin., has been appointed Clinical Assistant to the Chelsea Hospital for Women.
GURR, ALFRED S., M.D., M.R.C.S., has been appointed Honorary Physician to the British Consulate at Mostapha Supérieur, Algiers.
LAWRENCE, P. J., Brevet-Colonel, R.A.M.C., has been appointed Lecturer in Syphilology at the Royal Army Medical College.
LATHAM, ARTHUR, M.D., B.Ch. Cantab., F.R.C.P. Lond., has been appointed Advisory Physician to the Hospital for Diseases of the Throat, Golden-square.
LAWRENCE, ARTHUR GARNON, M.D. St. And., M.R.C.S., L.S.A., J.P., has been appointed Medical Officer of Health for Chesham.
MARTIN, JAMES PIERCE, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Districts of Box and Colerne by the Chippenham (Wilts) Board of Guardians.
MIDDLETON, E. W., M.D. Balt., has been appointed Clinical Assistant to the Chelsea Hospital for Women.
OSMOND, CHARLES HOLDWAY, L.R.P.S. Glasg., L.S.A., has been appointed a District Medical Officer by the Bristol Board of Guardians.
PATRICK, J. KING, M.B., Ch.B. Glasg., has been appointed Anaesthetist to the Glasgow Royal Infirmary.
PRINGLE, A. M. N., M.B., O.M. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ipswich District of the county of Suffolk.
SHORTY, H. F., M.D., B.S. Melb., has been appointed Resident Medical Officer to the Hospital for Diseases of the Throat, Golden-square, W.
SINGTON, HAROLD S., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH ROYAL UNITED HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and washing.
BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Assistant Physician.

BRIGHTON, HOVE, AND SUSSEX THROAT AND EAR HOSPITAL, Queen's-road.—House Surgeon, also Honorary Assistant Surgeon.
BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Surgeon. Salary £50 per annum, with board, rooms, and attendance. Also Assistant House Surgeon. Salary £50 per annum, with board, rooms, and attendance.
CARMARTHEN, CARDIGAN, AND PENNROSE JOINT COUNTIES LUXATIO ASYLUM, Carmarthen.—Junior Assistant Medical Officer. Salary £150, with rooms, board, washing, and attendance.
EDINBURGH SCHOOL BOARD.—Medical Officer. Salary £400.
FARRINGTON GENERAL DISPENSARY, Bartlett's Buildings, Holborn, E.C.—Honorary Physician.
GLOUCESTER GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £30 per annum, with board, residence, and washing.
HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, also Assistant Casualty Medical Officer, both unmarried. Salary in each case 25 guineas for eight months, with board and residence.
HULL ROYAL INFIRMARY.—Casualty House Surgeon. Salary £50, with board, and lodging.
LEITH HOSPITAL.—Surgeon in the Out-patient Department for six months. Salary £50 per annum, with board.
LONDON TEMPERANCE HOSPITAL.—Assistant House Surgeon. Salary at rate of £75 per annum.
LIVERPOOL DISPENSARY.—Head Surgeon, unmarried. Salary £200 per annum, with board and apartments. Also Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.
MANCHESTER EAR HOSPITAL.—Assistant Surgeon.
MANCHESTER EYE AND EAR HOSPITAL, 25, St. John-street, Manchester.—Honorary Aural Surgeon and Honorary Ophthalmic Surgeon. Also Anaesthetist. Salary £10 per annum.
NEWPORT BOROUGH ASYLUM, Caerleon (Mon.).—Assistant Medical Officer, unmarried. Salary £125 per annum, with board, apartments, and attendance.
NORFOLK AND NORWICH HOSPITAL.—Assistant House Surgeon for six months. Salary £20, with board, lodging, and washing.
NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Physician for Diseases of Women. Also Dental Surgeon.
ROCHDALE INFIRMARY.—House Surgeon, unmarried. Salary £160 per annum, with board, residence, and laundry.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Two Members of the Court of Examiners.
ROYAL SOUTH LONDON DISPENSARY.—Surgeon-in-Ordinary.
ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Honorary Physician.
SARATWAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Medical Registrar.
SHEFFIELD EAST-END BRANCH OF THE CHILDREN'S HOSPITAL.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.
SHEFFIELD UNIVERSITY OF SHEFFIELD.—Chair of Pathology.
STOKES-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL.—Junior House Surgeon. Salary £50 per annum, with board, apartments, and washing.
STROUD GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.
TRURO ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100 a year, with board and apartments.
VENTNOR ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Two Assistant Resident Medical Officers, unmarried. Salary £80 per annum each, with board and lodging.
VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Senior Resident Medical Officer. Salary £105, with board, residence, and washing. Also Surgeon to Out-patients.

WEST HARTLEPOOL CAXTERON HOSPITAL.—House Surgeon. Salary £100 per annum, with board, rooms, and washing.
WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House Surgeon. Salary £70 per annum, with rooms, board, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeon under the Factory and Workshop Act at Burford, in the county of Oxford; at Richmond, in the county of Surrey; and at Gomersal, in the county of York.

Births, Marriages, and Deaths.

BIRTHS.

CARPENTER.—On Jan. 3rd, at St. John's House, Blackheath, the wife of Sidney M. Carpenter, L.D.S. R.O.S. Eng., of a daughter.
HEWER.—On Dec. 31st, 1906, at Church-street, Stratford-on-Avon, the wife of Farnshaw Hewer, F.R.O.S., of a daughter.
SWELL.—On Jan. 4th, at Adeane Villa, Buckhurst Hill, the wife of R. Arthur Swell, M.B. Lond., of a son.

MARRIAGE.

DITTMAR-WILKINS.—On Jan. 2nd, at Hartley Wintney Church, Winchester, Hants, Frederick Dittmar, M.A., M.D., D.F.H., Catherine Beatrice Wilkins, M.A. Lond., daughter of Thomas Wilkins.

DEATHS.

MACDONALD.—On Jan. 2nd, at Inverary, Argyllshire, Francis Robertson MacDonald, M.D.
OLIVER.—On Jan. 4th, at Marsellie, Francis George Oliver, Superintending Physician, S.I. Railway, Trichinopoly, aged 43 years.
STEDMAN.—On Dec. 23rd, 1906, John Stedman, M.R.C.S., of Foke-down, Bournemouth, aged 68 years.

R.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

recent years their vegetarian habits have been largely departed from and some writers have in part attributed their recent vigour and success to this very circumstance. Referring to the Japanese, who are always adduced as models of plain living combined with efficiency, Professor Halliburton drew attention to the fact that no accurate information had been forthcoming as to whether the diet of our allies was so very poor in proteids as had been alleged. The supposition that the Japanese subsisted wholly on vegetable products could not be supported. Undoubtedly in recent years their vegetarian habits had been largely departed from, so that it was open to ask whether their recent vigour and success may not have had an exactly opposite origin to that so often attributed. On the question of milk Professor Halliburton urged that legislation was loudly called for in order to improve the supply and to prevent the undue addition of preservatives.

Obituary.

EDWARD ASHBY FARDON, M.R.C.S. ENG.,
L.R.C.P. LOND.

By the death of Mr. E. A. Fardon we have lost one of the ablest and most experienced of hospital administrators in the metropolis. For nearly 30 years he was resident medical officer of the Middlesex Hospital. He came of Quaker stock; his father, owning salt mines at Droitwich, held the office of mayor there, and his mother was a Bell of Alton, a descendant of one of the original Quakers, and a relative by marriage of Elizabeth Fry and the Guernseys of Earlsam. She died at the age of 84 years at Reigate and to the last wore the dress and lived the life of a typical "Friend."

Edward Ashby Fardon was born in 1846 and received his school education at the Quaker School at Sidcot in Somersetshire. On leaving school he joined his father in the salt works at Droitwich and there acquired business habits and knowledge which were of great value to him in after life. Here he worked till he was 27 years of age, but finding the business uncongenial he determined to enter the medical profession and defrayed the cost of his education partly by the money which he had managed to save and partly by winning scholarships and money prizes. He entered at the Middlesex Hospital in 1873, qualified as M.R.C.S. Eng. in 1878, and took the diploma of L.R.C.P. Lond. in 1879. He filled the office of house physician, junior and senior house surgeon, and that of resident obstetric assistant. While holding this office the post of resident medical officer to the hospital became vacant by the resignation of Mr. Henry Lucas, now surgeon to the West Suffolk Hospital, Bury St. Edmunds, and young Fardon was selected to fill the post. Here he found his life work, and although he had several tempting offers to engage in practice for which he had the best qualifications he steadily refused to entertain them and devoted himself with whole-heartedness to the interests of the Middlesex Hospital. Throughout his long term of office he enjoyed the complete confidence of the board of management, staff, resident staff, officials, and nurses, and to one and all of them he was ever ready to give the most sympathetic and enlightened assistance. Largely at his initiative, and always aided and guided by his counsel and wise supervision, many alterations and reforms have been effected in the hospital, the nursing department, and the school. Prominent among these may be mentioned the institution of the residential college for students, the Nurses' Institute and Home, the convalescent home, the laundry at Hendon, the removal of the kitchens from the basement to the upper floor of the hospital, additional wards, the operating theatres and sterilising apparatus, and the new cancer wing and cancer research laboratories. It may truly be said that there is no department of the hospital that does not bear distinct and lasting evidence of Fardon's administrative energy and ability. For several years he acted as honorary secretary to the Royal British Nurses' Association and was of great service in guiding the affairs of that body during a troubled period of its history.

Nearly two years ago it was discovered that Fardon had glycosuria and although he was carefully dieted and treated his friends were grieved to notice the only too evident signs of aging and lessened vigour. Last summer he contracted a "cold" which proved to be a tuberculous infection of the

lungs. In spite of all that the best advice could suggest and the most attentive care provide, the disease rapidly progressed and on Jan. 2nd he quietly passed away at St. Lawrence, Isle of Wight. Mr. Fardon will be greatly missed as a wise and experienced officer and mourned by many as a faithful friend. His judgment was never warped by selfishness, and his delight in helping others was unfeigned. He was laid to rest in the well-known churchyard of the old Church of St. Lawrence on Jan. 5th. At the same time a memorial service was held in the chapel of the Middlesex Hospital which was filled with a congregation, including many distinguished members of the board of the hospital, the staff, and a large number of past and present students and nurses.

ANDREW BALFOUR, M.D. EDIN., J.P.

Dr. Andrew Balfour, of Portobello, near Edinburgh, died on Dec. 26th, 1906, at the early age of 54 years. He was born in Hong-Kong, but in 1854, when he was two years old, his father, who was also a medical man, returning from the East, began practice in Portobello. The son graduated at the University of Edinburgh as M.B. and C.M. in 1873 and took the degree of M.D. in 1877. For some years he was associated with his father in practice and on the death of the latter about 20 years ago he entered into partnership with his brother, Dr. John H. Balfour, also of Portobello. Dr. Andrew Balfour held the appointments of medical officer of health of Portobello, Poor-law medical officer, and medical officer to some of the mining companies in the neighbourhood. While he was thus actively engaged in the general practice of his profession he took a prominent place in all local schemes having for their object the betterment of life. He was the means of founding the Portobello Working Men's Institute, he supported and encouraged reading and recreation rooms in the adjoining village of Niddrie, he was an active member of local bowling clubs, he started the local branch of the Boys' Brigade, and he taught a young men's Bible class for 30 years. He was an office bearer in the Free Church for many years but after the union of the Free Church and the United Presbyterian Church he transferred his membership to the Established Church. He also held office in the local Conservative Association and took an active part in local political life. He had a pleasant, friendly manner and no one doubted the honesty and straightforwardness of his opinions and actions. He leaves a widow and four children. The funeral took place on Dec. 29th in presence of a large and representative gathering.

SAMUEL EDWIN SOLLY, M.D. DENVER,
M.R.C.S. ENG., L.S.A.

Dr. Samuel E. Solly, who died recently in America, was the fourth of the seven sons of the late Mr. Samuel Solly, surgeon to St. Thomas's Hospital, who died in 1871. He was born on May 5th, 1845, and received his professional training at St. Thomas's Hospital, taking the diploma of M.R.C.S. Eng. in 1867, and that of L.S.A. in 1874. He at first practised in Savile-row where Mr. Solly, sen., also resided, but about the year 1874 ill-health caused him to seek a change of climate, and he accordingly settled at the small town of Colorado Springs, Colorado, U.S.A. Here he soon began to write on the subject of climatology, his first treatise being entitled "Manitou, Colorado, its Mineral Waters and Climate," which was published at Saint Louis in 1875. He was also the author of a "Handbook of Medical Climatology"; he contributed the article "Treatment of Tuberculosis" to Hare's "System of Therapeutics," and the article "Diseases of the Nose and Throat" to Loomie's "System of Medicine." His various writings have, no doubt, had a considerable effect in calling attention to the advantage of Colorado as a health resort. In 1886 he graduated as M.D. at the University of Denver. Dr. Solly took much interest in the work of various professional societies and organisations and had filled the office of president of the American Climatological Society, the Colorado State Medical Society, and the American Laryngological, Rhinological, and Otological Society.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. E. A. Atkinson, formerly professor of medicine and therapeutics in the University of Maryland,

TUESDAY (5th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Dr. H. Mackenzie: Clinique. (Medical). 5.15 P.M.: Lecture.—Dr. A. H. Chester: The Surgical Anatomy of the Temporal Bone, its Bearings on Suppuration (with lantern slides).

POST-GRADUATE COLLEGE (West London Hospital, Hammer-smith-road, W.).—10 A.M.: Dr. Moulton: Gynecological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: X Rays. Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Lecture.—Dr. Low: Insects as Carriers of Disease in Tropical Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—10.30 A.M.: Clinique.—Medical Out-patient (Dr. Auld). 2.30 P.M.: Surgical Operations (Mr. Carson); Clinique: Gynecological Out-patient (Dr. Giles). 3 P.M.: Clinique: Medical In-patient (Dr. Leslie). 4.30 P.M.: Lecture.—Dr. Forsyth: Working Value of the Diseased Heart.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. R. I. Hewlett: Medicine. 3.15 P.M.: Mr. Carless: Surgery. 4 P.M.: Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queens-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture.—Dr. Bouver: Cerebral Arterial Supply (Demonstration of Injected Hemispheres).

CHAMBER CROSS HOSPITAL.—4 P.M.: Demonstration.—Dr. Meit: (Medical). (Post-Graduate Course).

WEDNESDAY (6th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Mr. J. Berry: Clinique. (Surgical). 5.15 P.M.: Lecture.—Dr. E. Cantley: Asthma in Infancy and Childhood.

POST-GRADUATE COLLEGE (West London Hospital, Hammer-smith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Medical Diseases of Children. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. 5 P.M.: Dr. Peckard: Practical Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.). 2.30 P.M.: Cliniques.—Dermatological (Dr. Meschen), Ophthalmological (Mr. Brooks), Medical Out-patient (Dr. Whipham).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. P. Taylor: Medicine. 3.30 P.M.: Mr. Cargill: Ophthalmology. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

CENTRAL LONDON THEATRE AND EAR HOSPITAL (Grey's Inn-road, W.C.).—5 P.M.: Demonstration.—Mr. C. Nourse: Lecture.

THURSDAY (7th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Mr. Hutchison: Clinique. (Surgical). 5.15 P.M.: Lecture.—Mr. R. Jones (Liverpool): On the Treatment of some Paralytic Deformities.

POST-GRADUATE COLLEGE (West London Hospital, Hammer-smith-road, W.).—2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M.: Clinical Lecture.—Dr. Davis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 P.M.: Cliniques.—Gynecological Operations (Dr. Giles), Medical (Dr. Whiting), Surgical Out-patient (Mr. Carson). 4.30 P.M.: Lecture.—Mr. Edmunds: Diseases of the Thyroid Gland.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. G. Rankin: Medicine. 3.15 P.M.: Mr. W. Bennett: Surgery. 4 P.M.: Mr. M. Davidson: Radiography. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—6 P.M.: Chesterfield Lecture.—Dr. M. Dockrell: Syphilis. I. History and Primary Invasion (Constitutional and Local). Erythematous, I. Macular, and II. Maculo-Papular.

CHAMBER CROSS HOSPITAL.—4 P.M.: Mr. Waterhouse: Demonstration (Surgical). (Post-Graduate Course).

HOSPITAL FOR SICK CHILDREN (St. Ormond-street, W.C.).—4 P.M.: Lecture.—Dr. Voelcker: Ped and Ecto-carditis.

FRIDAY (8th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Dr. St. Clair Thomson: Clinique. (Throat).

POST-GRADUATE COLLEGE (West London Hospital, Hammer-smith-road, W.).—10 A.M.: Dr. Moulton: Gynecological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: X Rays. Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Clinical Lecture.—Mr. Armour.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 A.M.: Clinique.—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds); Cliniques.—Medical Out-patient (Dr. Auld), Ophthalmological (Mr. Brooks). 3 P.M.: Clinique.—Medical In-patient (Dr. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. E. Bradford: Medicine. 3.15 P.M.: Mr. McGervey: Surgery. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queens-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture.—Dr. Bouver: Hemiplegia.

SATURDAY (9th).—POST-GRADUATE COLLEGE (West London Hospital, Hammer-smith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

During the week marked copies of the following newspapers have been received: British Times and Mirror, North Devon Journal, Ovan Times, Western Daily Mercury, Yorkshire Post, Liverpool Daily Post and Mercury, Liverpool Courier, Scarborough Daily Echo, Literary Digest, The Tribune, Wakefield Express, Westmorland Gazette, Sheffield Independent, Exeter Gazette, Hereford

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1906, which was completed with the issue of Dec. 29th, were given in THE LANCET of Jan. 5th, 1907.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1906 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.O., are dealt with by them? Subscriptions paid to London or to local newsgents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£12 6	One Year	£14 8
Six Months	£6 3	Six Months	£7 4
Three Months	£3 2	Three Months	£3 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.O.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

Notes, Short Comments, and Answers to Correspondents.

THE COURTESY CALL.

To the Editors of THE LANCET.

SIRS.—The remarks of "A. S. S." in his letter to you on Dec. 22nd, 1906, contain advice to young practitioners respecting the importance of paying the courtesy call on their professional neighbours. Can I, in this writer's own words, ask for "your powerful influence to be exerted to impress this upon" those called upon—viz., that they should make a point of seeing that this courtesy call is duly returned. Personally, when I settled in a well-known Lancashire seaport town I called on the practitioners in the immediate neighbourhood of my predecessor's house and my own, and at least one-third of these calls remain unreturned to this day, and what makes it all the more serious is the fact that the chief delinquents were the senior men from whom one naturally would expect at least a knowledge of the commonest of courtesies. That this want of courtesy should accompany other breaches of medical etiquette is but natural, and it all goes to prove, as has been but feebly defended recently, the modern degeneracy of the present-day medical man. I feel certain if you opened your columns to a full correspondence regarding this subject the revelations which it could be possible to print would astonish even the most sceptical.

I am, Sirs, yours faithfully,

THEOLA W. ALBUM.

Dec. 23rd, 1906.

THE SIGNING OF MEDICAL BULLETINS.

To the Editors of THE LANCET.

SIRS.—A few years ago, at a meeting of a branch of the British Medical Association, and, I believe, also in your columns, there was a discussion about the appearance in the daily papers of the names of medical men in attendance upon people of any note. For a time matters improved, but lately the fault has reappeared very strongly. I could give you many instances during the last six months, but only in to-day's paper I see that Mr. Balfour and the Baroness Burdett-Coutts are ill and the names are carefully given of the medical men in attendance, as well as of the physicians in consultation. This is rather a marked contrast to the absence of names in the case of the recent illness of the Princess Royal. With ordinary care it can be avoided; but perhaps that is not wanted. The public scarcely care to know who is in attendance upon these and other sick people.

I am, Sirs, yours faithfully,

ANTI-ADVERTISER.

Dec. 31st, 1906.

LIGHTING A COUNTRY HOUSE.

To the Editors of THE LANCET.

SIRS.—Before deciding on the nature of illuminant to be fitted to a house in the country I should be glad to learn through the medium of your columns whether the medical profession hold any definite opinion on the two following points. 1. Is electric light in the composition of its rays more injurious or fatiguing to the eyes than acetylene, incandescent coal gas, or incandescent petrol vapour, and, if so, which of these four lights is the least injurious to the sight? It would be interesting to have comparisons of these with each other and with oil lamps and wax candles, and to know whether the fatigue that many people complain of as a result of electric light is merely due to improper shading. 2. Are any poisonous fumes given off as a result of the combustion of acetylene gas, coal gas, or petrol vapour, and, if so, which of the three is the least objectionable on this score?

I am, Sirs, yours faithfully,

LUMEN.

Jan. 3rd, 1907.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (14th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M.: Paper:—Dr. S. Phillips: Some Affections of the Pancreas.

TUESDAY (15th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover square, W.).—8.30 P.M.: Communications.—Dr. F. W. Anderson: Observations on MacConkey's Bile Salt Neutral Red Medium.—D. T. J. Horder: (1) Note on a Case of Typhoid Fever Diagnosed by Blood Culture in the Absence of Agglutination Reaction; (2) Third Case of Influenza Endocarditis Diagnosed by Blood Culture; (3) A Case of Gonococcal Endocarditis.—Mr. F. W. Twort: XI Incidence of Spontaneous Cancer in Mice.

MEDICO-LEGAL SOCIETY (22, Albemarle-street, W.).—8.30 P.M.: Exhibition of Medico-Legal Specimens. Discussion on Suicide and Sull (opened by Dr. C. Shaw).

WEDNESDAY (16th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover square, W.).—8 P.M.: Exhibition of Mounted Specimens by M. Rousselle. Annual Address.—The President: The Flowering Plant of the Mesozoic Age in the Light of Recent Discoveries.

FRIDAY (18th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos-street, Cavendish-square, W.).—5 P.M.: Cases will be shown by Dr. F. J. Poynton, Mr. H. S. Clogg, Dr. R. Cantley, Mr. F. L. Mummery, Dr. C. O. Hawthorne, Dr. T. R. Whipple, Dr. Carpenter, and others.

EPIDEMIOLOGICAL SOCIETY (11, Chandos-street, Cavendish-square, W.).—8.30 P.M.: Microscopical Demonstration.—Dr. J. B. Murray: Paper.—Dr. H. F. Bashford: Real and Apparent Differences in the Incidence of Cancer.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (14th).—MEDICAL GRADUATES' COLLEGE AND POLYTECHNIC (22, Chancery-street, W.C.).—4 P.M.: Dr. J. Galloway: Clinique (Skin). 5.15 P.M.: Lecture.—Dr. A. B. Kingsford: The Administration and Uses of Ethyl Chloride.

POST-GRADUATE COLLEGE (West London Hospital, Hammermith road, W.).—12 noon: Pathological Demonstration.—Dr. G. C. Low: 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays Operations. Mr. Dunn: Diseases of the Eye. 5 P.M.: Lectures.—Mr. Baldwin: Practical Surgery.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, Tottenham, N.E.).—9.30 A.M.: Clinique.—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Cliniques: Medical Out-patient (Dr. Whipple). Throat, Nose, and Ear (Mr. Carson). X Ray Demonstration (Dr. Friele). 3 P.M.: Clinique.—Medical In-patient (Dr. Chappell).

I. Lecture

ON THE

DIAGNOSIS OF TUMOURS OF THE SPINAL CORD.

Delivered at the National Hospital for the Paralysed and Epileptic on Oct. 16th, 1906,

By FREDERICK E. BATTEN, M.A.,
M.D. CANTAB., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE HOSPITAL.

THE diagnosis of tumours situated within the spinal canal is a matter of no difficulty in the later stages of the disease when all the characteristic symptoms—pain, gradual loss of power, and impairment of sensation—are present. In the earliest stage of the disease it is quite otherwise; pain is, or may be, the only symptom, and it may be impossible to detect even by the most careful examination any impairment in movement or of sensation. Such cases are in their early stages designated as sciatica, lumbago, muscular rheumatism, or "neuritis." Some are regarded as cases of hysteria or neurasthenia. In the later stages when actual weakness has appeared the cases are often said to be "myelitis," or peripheral neuritis, though even at this stage a diagnosis of neurosis is not uncommon.

Tumours of the spinal cord give rise to three definite sets of symptoms: (1) pain; (2) loss of power; and (3) loss of sensation. The relative degrees in which these three symptoms are present depend partly on the situation of the tumour and partly on the nature of the growth. The tumour may be situated outside the theca, within the theca, or within the spinal cord; the tumours in the first two situations commonly give rise to a considerable amount of pain, the latter to but little pain, although numerous exceptions to this rule are met with. The tumour may be single or multiple, innocent or malignant, slowly growing or of rapid growth. The tumours may grow in the cervical, dorsal, lumbar, or sacral regions of the spinal cord, or may be placed so low as to affect only the coccygeal region and the cauda equina.

From consideration of the above facts it will be seen how diverse the symptoms produced by a tumour of the spinal cord are and how different the clinical picture may be, in one case producing spastic paraplegia in the legs, in another a complete flaccid paralysis, in another a flaccid paralysis of an arm and a spastic condition in the legs. Before passing to the consideration of the cases about to be related it will be well to consider generally the three cardinal symptoms.

Pain in the back is a symptom of so great frequency without any sign of organic disease that little importance can be attached to it. Pain, however, which begins gradually, becomes accentuated on movement, on bending down, or on bending the head forward, and radiates down the legs or arms, should receive careful attention. Associated with this pain there may be actual tenderness on pressure on the spine and this may be so marked as to give rise to the possibility of caries of the vertebrae being present. The spine may in some cases be held rigid but in most cases free movement can be obtained. Pain is commonly the earliest symptom and frequently occurs for some considerable time before any other symptom manifests itself. "Girdle" pain may be present and may indicate the level of the lesion, but pain as a symptom does not often lend any special aid in the diagnosis of the position of the lesion; local tenderness may, however, be of localising value.

Loss of power in the legs is a complaint common to many diseases. When, however, on examination it is found that the loss of power is confined to, or at least affects, certain groups of muscles to a far greater extent than others, and when there is also a history of the gradual onset and increase of this weakness the condition is highly suggestive of the roots. In some cases the weakness and atrophy of muscles correspond exactly to the distribution of a nerve root or spinal segment; in such a case the seat of the lesion can be accurately determined or at least the highest point to which the lesion extends can be indicated.

Loss of sensation probably furnishes the best localising sign of the lesion. The examination of the patient for the appreciation of the various forms of sensation, tactile, heat and cold, and pain, is important. It is not enough to apply the tests so as to get a negative or positive result, but it is important to find the highest level of relative anaesthesia; the possibility of this depends upon the patient being a good witness.

The localising value of anaesthesia and analgesia in the distribution of a root area is of great importance. Pain, loss of power, and loss of sensation are the three chief symptoms; the condition of the reflexes and sphincters varies according to the situation of the tumour. The electrical reaction of the muscles also depends on the position of the lesion.

Having thus very shortly dealt with the cardinal symptoms let us pass to the consideration of the actual cases, and see in how far they correspond with the typical symptoms above described:—

CASE 1.—Male, aged 55 years: 15 months pain in back, shooting in character; 12 months difficulty in walking. Pain and tenderness especially over the sixth thoracic spine, weakness of legs, relative anaesthesia over legs and trunk to level of eighth thoracic segment. Increased knee-jerks, ankle clonus, extensor responses. Operation; removal of tumour; improvement.

The first case is that of a man aged 55 years. For the last 15 months the patient had had pain in the lower part of the back, and increasing difficulty in walking. He had influenza 18 months ago. In June, 1905, he had shooting pain in the sacral region and round the abdomen; the pain, he said, was easier when sitting up than when lying down, and it was especially severe after any shaking. The pain was throbbing in character, like a pulse beat. In September he had improved and was able to walk fairly well, but had pain when he stooped, or if he jarred the spine. In February, 1906, the pain recurred; he was unable to sit with comfort, and was easier standing up than when lying down. He had at this time slight delay in micturition. He came under observation in July.

On examination he was a fat, plethoric individual, very emotional at times, starting at the slightest noise. Nothing abnormal could be detected in the cranial nerves. All the muscles of the body were flabby and of poor tone but there was no definite wasting of any muscles or group of muscles. There was no tremor or rigidity. All movements of the head and neck were rather slow and limited; retraction of the head caused pain. Stooping was very limited and was done chiefly from the hip; the spine was moved as little as possible. All movements of the upper extremity were fair and of good precision. The movements of the lower extremity were feeble but all movements were capable of being performed. He walked with a somewhat stiff gait but it was rather the gait of a person who is afraid of pain produced by movement than that due to a spastic condition of the limbs. There was a sense of pain and constriction in the lower abdomen, not definitely localised. The pain was shooting in character and severe about the lower part of the spine. This pain was increased by movement, by coughing, or by laughing. Deep respiration was painful, chiefly on the left side. There was tenderness on pressure over the sixth dorsal spine and there was tenderness in the left lumbar region. There was general tenderness of the whole of the lower dorsal and lumbar region. There was slight relative anaesthesia and analgesia from the eighth rib downward. (See Fig. 1.)

The epigastric abdominal reflex was present, but the abdominal reflex below the eighth dorsal segment where the anaesthesia began was lost. The knee-jerks and ankle-jerks were very brisk; there was ankle clonus and the plantar reflexes gave extensor responses. The sphincters acted normally, but if the patient had to hold urine for a long time there was delay in starting micturition. Three small subcutaneous tumours were present in the wall of the abdomen; these were tender on manipulation. Under treatment his general condition improved, but the symptoms remained the same.

On August 20th Mr. Percy W. G. Sargent removed one of the subcutaneous tumours in the abdomen; this proved to be a lipoma. An incision was made in the middle line behind from the fifth to the tenth dorsal spine. The spine of the seventh dorsal appeared more prominent than the rest. The laminae of the fifth, sixth, seventh, and eighth vertebrae were removed. No pulsation was seen in the dura mater which appeared unusually thick as if infiltrated with growth. An incision was made into the dura mater and the cord below appeared quite normal. It was

seat of the lesion may be above that indicated by the symptoms when the lesion is centrally situated.

CASE 3.—Male, aged 30 years. Four months previously slight injury, followed by difficulty in micturition, severe pain in back, and loss of power in legs; syphilis eight years ago. On examination, partial loss of pain in both legs, loss of sensation of root distribution in both legs, absent knee-jerks, and incontinence of urine. Treatment by mercurial inunction; improvement.

The third case is that of a man aged 30 years. In May, 1905, the patient was kicked in the perineum. The kick was not severe and was unattended by any bruising. Three days later he had difficulty in emptying the bladder and then failed to pass any urine. A catheter was passed and three pints of urine were drawn off. He was then laid up in bed for two weeks. On getting up he noticed that his legs were weak though he was still able to run. Since that time he had steadily got weaker and was now quite unable to walk and could not move the right foot at all. He had severe pain in the lower part of the abdomen and pain was increased by movement. He had had malaria in 1897 and syphilis in 1898.

On examination the patient was, so far as the upper extremities were concerned, a well-made man with excellent muscular development. Nothing could be found abnormal in the head, neck, thorax, or upper extremities. He was unable to walk or stand but could when lying in bed move the left leg in any direction required. All movements were, however, feeble from the hip downwards and it required but little resistance to prevent the movement being performed. The movements of the right leg were feebler than those of the left and he was quite unable to dorsiflex the foot on the right side. There was general wasting of both legs but no localised atrophy of any individual muscle or group of muscles. The abdominal muscles contracted well but there was slight elevation of the umbilicus on attempting to sit up, indicating weakness of the lower part of the rectus abdominis. The knee-jerks and ankle-jerks were absent on both sides. The plantar reflex was absent on the right and gave a flexor response on the left. The abdominal reflexes were present but difficult to obtain. There were dribbling incontinence of urine and incontinence of faeces after aperients. There was relative anaesthesia over the area supplied by the fourth and fifth lumbar and first, second, third, fourth, and fifth sacral segments of the cord on the right side and over the first, second, third, fourth, and fifth sacral segments on the left side. (See Fig. 3.)

FIG. 3.

Relative loss of all forms of sensation over shaded parts—viz., over the first, second, third, fourth, and fifth sacral root areas on both sides, and also over the fourth and fifth lumbar areas on the right side.

The position of the lesion was in this case probably at the level of the second and third lumbar segments and was syphilitic in nature. Mercurial treatment was adopted and

the patient rapidly improved and is now able to walk relatively well.

CASE 4.—Girl, aged 15 years; nine months pain; three months loss of power; incontinence of urine; alteration in sensation. On examination flaccid paralysis of both legs, wasting of muscles, and loss of sensation to twelfth dorsal segment. Operation; removal of extra-theal tumour.

The fourth case is that of a girl, 15 years of age. In November, 1905, the patient first began to complain of pain on the left side going down to the left hip. From this she recovered, but in February, 1906, she again had pain over the left side and the left groin. She was at this time generally out of health, but had no actual loss of power. On June 4th she fell from a swing but did not seem to injure herself. On the 12th she went to a swimming bath and on that evening had severe pain in the back and could not sleep. On July 9th she noticed dragging of the legs and she could not stand on tiptoe. On the 12th she woke up with severe pain in the back and inability to move her legs and on this day she passed urine in bed without being conscious of the act. The numbness of the legs was first noticed on this day.

On admission to the hospital on Sept. 24th she had the appearance of a rather overgrown girl for her age. Her muscular development was poor. Nothing abnormal could be detected above the umbilicus. There was complete flaccid paralysis of both legs with general wasting of muscles. The upper three-quarters of the rectus abdominis muscle acted well and the umbilicus was slightly raised on attempting to sit up; the lower quarter was weak. There were complete anaesthesia and analgesia to the level of the twelfth thoracic segment on both sides (see Fig. 4). There

FIG. 4.

Complete loss of all forms of sensation over the blackened areas—i.e., to the twelfth dorsal segment. 12.sp. = tender spots at the level of the ninth and tenth dorsal and first, second, and third lumbar spines.

was tenderness on pressure over the ninth to tenth thoracic spines and also over the second and third lumbar. All the deep reflexes were abolished in the legs and the plantar reflexes were absent. The upper abdominal reflexes were obtained but the lower were absent. An electrical examination showed complete loss of electrical excitability to faradism in all muscles of the legs and altered reaction to galvanism. There was complete incontinence of urine and faeces.

Remarks.—The complete loss of sensation below the level of the twelfth dorsal segment and the complete loss of power below the same level with loss of sphincter control and loss of faradic excitability of the muscles would point to either a complete physiological or anatomical transverse lesion at the level of the twelfth dorsal segment or to the involvement of all the roots of the cauda equina below that level. It is impossible in the later stages of the disease to distinguish between these lesions, although in the earlier stages when

now found possible to strip the growth off from the dura mater; the growth consisted of an oval plaque, about one and a half inches long, lying on the dorsal surface of the dura mater. After this had been removed a small oval tumour of about the size of a small bean lay on the left side at the level of the seventh thoracic lamina. This tumour contained a small bead of pus or broken down growth. The patient after operation had pain and retention of urine for some days but then made a good recovery. He was free

FIG. 1.

Relative loss to all forms of sensation over the shaded area.
Ls. = tender spot at the level of the sixth dorsal spine.

from pain but still had two months after the operation considerable weakness of the legs with increased reflexes, ankle clonus, and extensor responses.

The growth was examined by Dr. T. Grainger Stewart and the following is his report: "The growth is a typical fibro-myxo-sarcoma. The dura is infiltrated by the growth and shows an increase of fibrous tissue. Though in great part the growth is a fibro-sarcoma, at places the tumour cells have undergone a myxomatous degeneration."

The leading feature in this case was pain, the loss of power being only of moderate severity and there was a relative amount of anaesthesia. The diagnosis was based on the pain, the gradual increasing loss of power, and the impairment of sensation. The points of localising value were the tenderness over the sixth thoracic spine and the relative anaesthesia to the eighth thoracic segment.

CASE 2.—Girl, aged nine years; ten months pain; difficulty in walking; five months incontinence of urine. On examination, loss of power in legs; spastic; flexed; exaggerated knee-jerks; ankle clonus; extensor responses; loss of sensation; incontinence of urine. Operation; central tumour of spinal cord; no improvement.

The second case is that of a girl nine years old. In June, 1904, she fell and bruised her back but no further trouble resulted. In October she first began to complain of pain in the back and she walked badly, dragging the toes of the right foot; she had pain in both thighs. In December her gait was very much impaired and from then to March, 1905, she was in the Victoria Hospital for Children, and whilst in the hospital she developed incontinence of urine and faeces.

The child was admitted to the National Hospital in August, 1905, and on examination presented nothing abnormal about the head, neck, or upper extremities. The abdominal muscles acted well. There was but little power of movement of the legs from the thigh downwards. The legs were flexed and rigid and could not be extended either actively or passively; there was slight general but no localised wasting. The muscles retained their mechanical irritability. The knee-jerks were brisk and equal; the ankle-jerks were active, and ankle clonus was present on both sides and the plantar reflex gave an extensor response. There was reflex incontinence of urine and faeces; the

tonicity of the sphincter ani was natural. There was loss of tactile (cotton wool) sensation over all the sacral roots on both sides and also over the fifth lumbar root on the right side; there was partial analgesia over these areas but the patient was conscious of a pin point. (See Fig. 2.) A bed sore was present over the right buttock. There was no tenderness or deformity of the spine.

Remarks.—The cardinal symptoms of pressure on the spinal cord were present—pain, gradual loss of power, and loss of sensation. The important question was, however, What was the situation and nature of the lesion? First, pain in the thighs would seem to indicate a lesion in the lumbosacral region of the cord on both sides, possibly an extensive lesion. Secondly, the loss of power in the legs was out of all proportion to the wasting of muscles—a fact which would indicate that the lesion was situated above the lumbar segment of the cord; on the other hand, the abdominal muscles acted well, and hence the lesion should be below the twelfth thoracic segment. Again, the reflexes of the legs were all exaggerated and the limbs spastic; the presence of the knee-jerks would certainly indicate that the lesion was above the third lumbar segment. Thirdly, anaesthesia was present in the fifth lumbar root on the right side and in all the sacral roots of both sides, a fact pointing to the involvement of those posterior roots or segments of the cord.

From consideration of the above facts it was considered probable that the lesion was at the level of the twelfth thoracic segment. With regard to the nature of the lesion,

FIG. 2.

Loss of tactile sensation over the shaded portions—viz., the first, second, third, fourth, and fifth sacral root areas on both sides, and also over the fifth lumbar root on the right side.

caries of the vertebrae is by far the most common cause of paraplegia in children. The absence of any sign of caries of the vertebrae, however, led to the diagnosis of tumour.

The operation was performed at the highest level indicated by the symptoms and Mr. Horace S. Collier removed the eleventh and twelfth dorsal laminae. The cord was found to be non-pulsatile. The laminae of all the vertebrae to the sixth dorsal were then removed and the cord was found to be pulsating; at about the level of the seventh dorsal it appeared to be distended. A small incision was made into the posterior column at this level and a small amount of the transparent gelatinous substance forced its way out. The tumour was situated within the spinal cord and was irremovable. The microscope showed that the tumour was gliomatous in nature.

In this case the sensory symptoms indicated a lesion at the level of the fifth lumbar segment, the motor symptoms a lesion at the level of the twelfth thoracic; the actual seat of the lesion was the seventh thoracic segment. The case is of special value as demonstrating the fact how far the actual

eclipsed clinical experience. Meanwhile it was cold comfort to the patient to feel that he was possibly viewed by his medical attendant as an interesting pathological specimen and that the macroscopical and microscopical appearance of his ailing viscera was accurately known.

At this time the great rise of surgery took place. Surgery having found salvation in bacteriological cleanliness, such cleanliness being surgical godliness, surgeons mounted from strength to strength, and having amputated everything and anchored the rest now sigh only for new viscera to conquer. Small wonder that the surgeon who could offer active assistance was often preferred to the practitioner of passive resistance. But there is no progression without retrogression, and this stage in the evolution of medical science was the natural order of development and inevitable. As structure precedes function and anatomy precedes physiology, so morbid anatomy of the organ and then of the cell preceded chemical pathology and pharmacology of the cell. We are now in the chemical age and numerous workers are constantly adding to our knowledge; so much so that it is difficult for anyone to collect the facts, much more to digest them or apply them in practice. And yet, as I apprehend it, that is the particular duty of the general practitioner—viz., to apply new facts to old diseases.

The study of medicine is the study of life, and its foundation stone is the unit of life, the living cell. If the mystery of life is to be solved it will be by the experimental examination of the simplest form of life. The discovery that every tissue, every cell, has its own special ferment, is of far-reaching importance in explaining much that was mysterious in physiology and pathology and accentuates again the importance of chemistry in explaining vital phenomena. When medicine and physiology are written anew, in leaded type, we shall be told the relations that one ferment bears to another. Pawlow has already done this for us as regards the digestive ferments. And it is by virtue of this special ferment that each cell is able to select out of the food-stuffs such material as it can transform into energy. The corollary of this is true, that an organ or tissue may fail to perform its function from lack of special fuel to make the ferment. It has been pointed out that during the involution or atrophy of an organ the symptoms which arise may be due to the absorption of the tissue and its passing into the general circulation; absorption of kidney tissue, for example, produces increased arterial tension; liver substance lowers it. Recently, we have all seen the involution of an enlarged thyroid give rise to all the signs attributable to large doses of thyroid extract. It occurred to me that it was strange that during the involution of the gravid uterus that symptom did not arise; if this theory be correct, may it be that the product of the uterine tissue is the natural excitant of the mammary gland function? The degree of disturbance that arises may vary according to the previous activity of the organ or the rapid excretion or neutralisation of its internal secretion.

Recent researches, I think, emphasise the importance of little things. That is well shown in the effect of abstracting lime salts from the blood, in producing hæmorrhage by injudicious diet. We might have foreseen this by noting the effect of improper diet in producing scurvy. 15 grains of lime lactate are recommended as an antidote to morning headache after too much alcohol, alcohol producing slight oedema of tissues. Another point in practice is the relation of NaCl to exudations and its effect in modifying remedies. That such simple substances either withheld or abstracted from the blood can produce such far-reaching effects makes one hopeful of controlling the beginning of disease as our knowledge increases. It is new to me that acetonuria is derived, not from carbohydrates, but from the metabolism of fat, thus giving sanction to clinical experience that in such diabetic conditions it is not wise to withhold altogether carbohydrates from the diet. Professor J. B. Leathes says: "In practically all forms of acetonuria increasing the amount of fat in the food intensifies the condition. The disorder in carry out the final steps in the progressive oxidation of the fatty acids, and brought about by overtaking its powers." From the same authority we learn "that fatty degradation is not a degradation conversion of the proteins of the cells into fat, but that in fatty heart and tissues and damped down, so to speak, for the purpose of supplying source of energy to the organ, from where it was only storage fat, to where it would be used up if the

catabolic activity of the cells were normal, but the catabolic changes which liberate energy by the demolition of fatty acids fail, and the imported fat accumulates, because it cannot be used up. Ph or As, or diphtheria toxin may act as negative catalysing agents, and retard the rate at which a reaction normal to the cells take place, and so by attacking a vital function, poison the cells by robbing them of their power of using what in normal conditions would be their principal source of energy." Again, "the catabolism of proteids takes place within the cells of the various tissues by means of enzymes native to the cell. This process has been termed autolysis. And these enzymes are the agents in the resolution of pneumonic exudation. The changes in the liver in Ph poisoning are due to autolytic activity getting out of control." This stimulating effect of phosphorus on autolysis gives support to the old therapeutic practice of giving phosphorus in delayed resolution in pneumonia. "Autolysis may account for the liquefaction of pus, the softening and breaking-down of new growths, and the absorption of infarcts and thrombosed parts. The absorption of gummata by means of KI has been attributed to the influence of the drug on autolysis."

As another instance of the importance of bio-chemistry to medicine I mention the interesting suggestion of Professor B. Moore of Liverpool as to the possible causal relation of auto-catalysis and infection. "In the course of any chemical reaction the products formed may themselves in certain cases act as catalysts and alter the velocity of the reaction. Such a process has been termed auto-catalysis. When the substance formed in the reaction acts as a positive catalyst the course of the reaction assumes an accelerando type. The course of such auto-catalytic reactions bears a close analogy to the phenomena of fever. Examples of such auto-catalytic reactions are seen in the tendency of many explosive substances to spontaneous combustion or explosion. Thus if gun-cotton be not most carefully washed free from oxides of nitrogen these products, present in minute quantity at first, may set up a slow and at first inappreciable reaction which, slumbering at first, gradually increases in velocity, and finally fires off the gun-cotton. Such a process of auto-catalysis induced by a trace of enzyme may be the means of infection and of the reproduction of the virus in many of those infectious diseases, such as the acute exanthemata, in which no germ has been as yet shown to have causal connexion. The incubation period would be that required for the production of the auto-catalyst in sufficient quantity to cause a general reaction with the tissue cells. The auto-catalyst would act as the toxin of the disease; the tissue cells would react to it and produce the antitoxin until the toxin was neutralised or rendered inert. Variations in immunity would, as in parasitic infection, depend upon the individual variations in the blood as a suitable medium for such a reaction, upon the presence or absence of an anti-body at the outset capable of neutralising the trace of auto-catalysts bearing the infection, and upon the reactive power of the tissue cells to the auto-catalyst or toxin." The chemical theory of disease will explain many of the so-called functional diseases—diseases where no structural alteration is manifest, a ferment gone wrong, or an internal secretion in excess or absent, disturbing the harmonious action of the part. We hear much less than we did of idiopathic inflammations, the idiopathicitis is that is most popular amongst the "unco gild" being idiopathic urethritis and vaginitis. But this is laymen's pathology.

Our knowledge of the causes of sterility in apparently robust and vigorous couples is very unsatisfactory. I regret the current fashion of declaring in all these cases that stenosis of the cervical canal exists and that dilatation and curetting are necessary. Conception rarely follows the operation. The cause of sterility is probably much more subtle and delicate. The spermatozoon is very sensitive to both chemical and galvanic stimuli. If a galvanic current is passed through a tube containing spermatozoa the latter place themselves with their heads towards the anode and their tails to the cathode, reverse the current and they reverse their position (galvanotaxis). They have the property also of always heading up against a flowing stream (barotaxis). The spermatozoon seeks the ovum, and when the conditions are favourable is led in the right path by the chemotactic action which the metabolic products of the ovum exert upon the freely-moving sperm cell. Many chemical substances induce only positive chemotaxis, others only negative. It is evident much may happen before the spermatozoon reaches the ovum. That sterility is not always

the plantar reflex is still present the occurrence of an extensor response would point to a transverse lesion rather than to a lesion affecting the roots.

Mr. Sargent made an incision over the eighth dorsal spine and removed the laminae of the seventh, eighth, ninth, and tenth vertebrae and exposed a tumour lying outside the theca and extending along the twelfth left posterior root. The tumour was dissected off and removed. Good pulsation returned after removal of the tumour.

Microscopical examination of the tumour showed it to be a sarcoma, composed of large round cells with but little connective tissue between them. In many places the growth was formed of dense connective tissue which surrounded and pressed upon clumps of the tumour cells which in places show degenerative changes.

These four cases illustrate well the characteristic symptoms of spinal tumour—gradual and increasing pains, gradual and increasing loss of power, and impairment of sensation. In the first two cases there was a spastic paralysis with increased knee-jerks and extensor response; in the last two there was flaccid paralysis with loss of deep reflexes. The difference in the symptoms depending on the position of the lesion. The sensory symptoms gave the most accurate localisation in three cases, but was at fault in the case in which the tumour was situated within the spinal cord.

The differential diagnosis of tumours situated within the spinal cord from those situated outside is one of considerable difficulty. It was at one time thought that the loss of perception of heat and cold and the retention of tactile sensation was indicative of a lesion within the spinal cord. Although none of the cases in the present series prove this point it is certain that no great reliance can be placed on this symptom and extra-medullary lesions may in some cases give rise to dissociated anaesthesia or to the Brown-Séquard phenomenon.

In Case 4 it will be noticed that the paralysis manifested itself rather rapidly and, according to the history, became complete in from three to four days. It is possible that this is accounted for by the pressure on the cord becoming so great as to give rise to a physiological complete transverse lesion, and it will be noticed that at this time all sense of the action of micturition was lost.

The importance of early diagnosis in cases of spinal tumour is great, since from delay irreparable damage may be done to the spinal cord by the prolonged pressure of the tumour. So long as the spastic condition remains this is evidence of conduction through the cord at the seat of the lesion, but if a flaccid paralysis supervenes on a spastic condition it indicates that a physiologically complete transverse lesion of the cord has taken place and unless rapidly relieved will result in a complete anatomical transverse lesion from which there can be no hope of recovery. As in the oranium the occurrence of headache with the gradual onset of localised weakness suggests the presence of an intracranial neoplasm, so in the spinal cord the occurrence of pain and the gradual onset of weakness should always suggest the possibility of a spinal growth.

Treatment.—In cases in which there is definite specific infection mercurial inunction should be pushed to salivation; sometimes no improvement will be manifest till salivation has begun. Even in these cases if a flaccid paralysis should supervene on a spastic condition no time should be lost in opening the spinal canal and relieving pressure on the cord. In other cases iodide of potassium should be given in large doses. In the majority of cases operation is indicated and should be performed at the earliest moment compatible with accurate diagnosis. The seat of operation should be at the highest level indicated by any symptom.

For permission to refer to one of the above cases I am indebted to Dr. Thomas Buzzard and to another to Dr. J. A. Ormerod. For the careful notes I am indebted to my house physician, Dr. George Hall.

BORIC ACID IN SAUSAGES.—At Falmouth, on Jan. 7th, a butcher was summoned for selling "German sausage" containing 45 grains of boric acid per pound. The magistrates considered that the defendant had used the preservative in ignorance and the case was dismissed on his paying the costs of the court.

ABSTRACT OF

A Presidential Address

ON

SCEPTICISM IN THERAPEUTICS.

Recently delivered before the Leeds and West Riding Medical-Chirurgical Society.

By AUGUSTUS H. BAMPTON, M.D.,
M.Ch.R.U.I., M.O.H.

GENTLEMEN,—Scepticism is in the air. Even in this society, if any daring member has introduced a subject bearing on medical treatment it has been with an apologetic air and humble mien, well knowing that if his remarks had any reference to the utility of drugs in the treatment of disease they would be subjected to good-humoured banter and received by those sitting in the seat of the scornful with amused incredulity—scepticism not entirely confined to the surgeons whose mental environment, training, and temperament would discount much of it, but the chief critics have been those of the medical household. The general practitioner, in the meanwhile, has said little, pondered deeply, and prescribed more or less on the even tenour of his way. Practising both branches of the profession, as far as he knows how, he may claim to be like "Iolanthe," mortal as far as the waist and immortal below. Which half of him is medical and which surgical I leave you to decide.

If I believed that we were unable to modify, arrest, or favourably influence the progress of disease by therapeutic means, then our occupation as physician has gone, and I for one would not accept the position of a kind of superior nurse, with a watching brief, which in the past eminent men in our profession (who knew too much pathology and too little pharmacology) have assigned to us. I know of no more unsatisfactory position either to client or advocate than that of holding a watching brief. And if we are only nurses, let us be honest and say so, and not accept fees for healing and wonder-working which in the nature of things we are unable to accomplish. I do not think that at any time we were justified in assuming an attitude of helplessness or masterly inactivity. And although our treatment then, as now in part, may be stigmatised *empirical*, it was none the less founded upon careful clinical experience and we showed shrewd common sense in not being off with the old love before we were sure of the new one of experimental research. There are other of our habits besides drug taking which are equally empirical; for instance, our habits of eating and drinking, clothing, and giving in marriage, and these will continue in spite of the stigma of empiricism. The work done in the near past and present fills one with hope that our weapons will soon be weapons of precision.

It is evident that we are passing through as great a revolution in medicine as that which has transformed surgery in the last 25 years, and the reason of it is that, like the surgeons, we are getting back to first principles, we are realising in practice what we have long known in theory, that man is an organised collection of differentiated and highly specialised cells, and that cellular action is governed by physical laws and chemical processes and are profoundly influenced by slight causes, and that nine-tenths of disease are due to the interaction of cells and their products and germs and their products, chemistry being the interpreter of these phenomena. Barely 50 years ago belief in drugs and energetic treatment was the faith and practice of the majority of the profession. It was the rise of the pathological school and the study of morbid anatomy that shook the faith of the succeeding generation of practitioners, viewing only the last stages of disease and seeing structural alteration in the *mass*. It was thought unreasonable to imagine that any pharmaceutical product could have any influence whatever on such profound structural changes in vital organs. It was argued that the cause of many diseases being unknown, therefore the remedies were irrational. And it was noted that many patients got well from acute disease without any treatment whatever. Much more importance was attached to pathology than to therapeutics at the examinations and a pronounced Agnostic frequently filled the chair of pharmacology. Morbid anatomy for the moment

was known and practised thousands of years ago by the Indians and Chinese, and was quite a common practice in the Middle Ages. As time went on there was evolved the method of inoculation of cow-pox to protect against small-pox and, more recently, the use of antitoxic sera and various forms of vaccines to neutralise the effects of diseases which had already invaded the organism. The cure by such means of an already established disease is, of course, of the greatest importance to the community and various explanations have been given of the destruction of bacteria within the organism.

According to some, it depends on some action of the serum, according to others on the activity of the phagocytes which ingest and destroy the bacteria, while others hold that both serum and phagocytes are necessary. Behring showed that anthrax bacilli grow well on the blood serum of animals which are susceptible to anthrax inoculation but cannot be got to grow on the serum of white rats which have been rendered immune to anthrax. He also showed that while one particular serum is fatal to certain varieties of micro-organisms it is powerless to inhibit the growth of certain other organisms and that a definite amount of serum is only capable of dealing with a certain definite number of bacteria, so that if bacteria in excess of this number are introduced they grow and multiply actively. In other words, the immunity thus conferred depends upon the ratio between the number of micro-organisms and the quantity of the substance identical to their growth contained in the fluid.

It has been shown that the destruction of the typhoid and cholera bacillus can be brought about by lysins which are present in the corresponding immune sera after artificial inoculation (Pfeiffer) and lysins have been assumed to exist in other diseases also. In the case of diphtheria and tetanus antitoxins are employed clinically which neutralise the respective toxins. Anti-bacterial substances have by some been held to exist within the phagocytes in the form of ferments and in certain circumstances to be secreted by them. According to Metschnikoff the destruction of bacteria is carried out by the phagocytes alone which have in the case of natural immunity been pictured as carrying on a war with the microbes that are attempting to invade the organism. Relying on the experiments of Bordet and Gengou he ascribed the whole protective influence to the phagocytes alone, but it has since been conclusively shown that these, washed absolutely free from serum and the substances contained in it, have of themselves no phagocytic action on bacteria.

The theory, which is a combination of Metschnikoff's phagocyte theory and Behring's humoral theory, receives strong confirmation from some experiments of Buchner. By suitable chemical stimulation he was able to cause the secretion into the pleural cavity of rabbits and dogs of leucocyte-containing exudates which possessed bactericidal powers stronger even than those of the blood or serum of the same animal. Under these conditions, however, phagocytosis could be observed to be proceeding actively and the question immediately arose as to how far the bactericidal qualities of the fluid depended upon phagocytosis and how far upon the contained alexins or anti-bodies. The question seemed to be settled by freezing the fluid and by this means killing the leucocytes but not injuring the alexins, and then again testing its bactericidal powers. These were found to be in no way diminished, and, inasmuch as the leucocytes had been killed, the capacity of the fluid to destroy bacteria must necessarily depend upon the contained anti-bodies. But even if phagocytosis is merely a secondary phenomenon and the destruction of bacteria is brought about by poisonous substances circulating in the fluids of the body, there is a considerable amount of evidence which goes to show that these poisons are secreted by the leucocytes. The influx, therefore, of these white corpuscles to an infected area means an increased secretion of substances poisonous to the invading micro-organism and increased powers of resisting disease. One substance, opsonin or immune body, is, together with the complement present in every normal serum and accounts for its bacteriolytic and hemolytic action. Numberless observers have shown the presence of such a substance, which becomes attached to the bacteria in such a way as to render them capable of absorption and destruction by the phagocytes, but whether this action is entirely due to immune body or whether free complement also takes part in the preparation of the bacteria is not so certain. It would, at any rate, increase the strength of action of the immune body, even if it were

not absolutely necessary. I have drawn no distinction between opsonin and immune body, not because they are identical, but because up to the present it has not been shown that they are different. It has been asserted by Wright and Douglas that opsonins are thermo-labile—i.e., destroyed by heat—and therefore differ essentially from immune body. They state that if the serum be heated to 60° C. for a quarter of an hour and a tube containing the usual proportions of washed corpuscles, bacterial emulsion, and heated serum be incubated for 15 minutes no bacteria will have been ingested by the phagocytes because the opsonin necessary for their preparation has been destroyed by heat. If this were true it would make it probable that the opsonin is either of the nature of complement or receptor of a fourth order. Dean has, however, in an admirable piece of work, shown that when fresh serum, either normal or immune, is heated to 60° C. for various periods there is a great fall, as estimated by Wright and Douglas's method, in the amount of activating substance in the first two minutes and after that the curves run almost parallel to the base line. In the case of normal serum the fall is so great that the curve may reach the base line. The fall in the curve does not, however, indicate complete destruction of the substance, as was stated by Bulloch and Atkin, but merely indicates that the substance has reached a concentration below that demonstrable by Wright and Douglas's method. Horse serum after heating to 60° C. for as much as four hours still contains a considerable amount of the substance, so that, as judged by the effect of heat, there is no reason to distinguish between the opsonin of normal serum and the active substance of immune serum.

Whatever the exact nature of opsonins, they undoubtedly act on the bacteria in such a way as to enable them to be taken up by the phagocytes. This is proved by the following experiment of Wright and Douglas. Two tubes are incubated for a quarter of an hour at 37° C., the one containing three volumes of normal serum, plus one volume of staphylococcus emulsion (previously heated to 75° C. and cooled), the other containing three volumes of serum which has been heated to 60° C., plus one volume of staphylococcus emulsion (previously heated to 75° C. and cooled). On removal from the incubator the first tube (containing normal serum) is heated to 60° C. and cooled. The contents of each tube are then added to three volumes of white blood corpuscles and the number of staphylococci taken up per phagocyte counted. It is found that the number of staphylococci taken up in the second case is only one-seventh as compared to that taken up in the first case: in other words, the opsonin acts directly on the bacterium. It seems that opsonins are specific and in a considerable number of infections specific opsonins have been demonstrated. Variations in the amount of opsonins in the blood are not necessarily associated with variations in the number of leucocytes.

An increase of the opsonic content of the blood serum can be brought about by the injection into the organism of vaccines. Of these the best known is the "old" tuberculin of Koch, which he employed as an injection in the treatment of tuberculous patients when first he introduced the tuberculin method some 15 years ago. The preparation is a clear brownish fluid, somewhat viscous from the presence of glycerine, and is diluted down before use according to the required dose, bearing in mind that the dilutions must be freshly prepared. It is obtained by growing the tubercle bacilli in glycerine-veal broth in the presence of a sufficiency of oxygen for from 6 to 12 weeks, and then sterilising, evaporating, and passing twice through a Chamberland filter. The resulting fluid is practically a solution in glycerine of the cellular metabolic products of the organism and contains one or more toxic bodies which may be either of the nature of a ferment, albumose, or alkaloid. It is used chiefly for diagnostic purposes in doses of one cubic millimetre, which in tuberculous patients produce a rise of temperature and inflammatory reaction of neighbouring tuberculous lesions. If this reaction is absent double the dose is given two days afterwards and, if there is still no reaction, double the last dose is given after another two days. If reaction does not show itself after the third dose the patient is probably not tuberculous. Although this "old" tuberculin is sterilised and there is therefore no danger of inoculating the patient with tubercle by its use, it is much less used for therapeutic treatment than tuberculin Koch T.R., which is prepared from a virulent culture of tubercle by drying, grinding up the

due to gross mechanical causes is often shown by subsequent proceedings that lead to the divorce court, which proceedings may be explained, if not justified, from the biological point of view.

Have we not been unduly cautious and prejudiced in general practice against the use of tuberculin? Its use has certainly not been generally adopted in this country, although we quickly grasped the utility of using antitoxin in diphtheria. It has been stated that gouty people are never tuberculous. It would be interesting to test the truth of this statement by means of the opsonin test. As medical men all our practice, theory and treatment, is based upon the view that we have to deal with machines out of order; this function has to be put right or that part lopped off. Transcendental medicine or surgery has not yet been written. If vital phenomena are supernatural then our remedies should be supernatural. And where are we to find them? Treatment by suggestion, endeavouring to make patients believe and act upon a delusion, is perilously like playing at insanity.

The life of the individual is the sum total of the activities of his constituent cells. A man is as old as his cells. The cell is the element of living substance. All living substance exists in cells and all the functions of living substance originate in the elementary vital phenomena of the cells. Here we are on sure ground. These are the first principles of medicine. As a working hypothesis the mechanical view of life is the only practical one for medical men. The question of the unity of nature is not called in question.

Hear what a practical bio-chemist says bearing on the point speaking of metabolism. Professor Leathes says: "It implies and gently insists on the idea that all the phenomena of life are at bottom chemical reactions, when a muscle twitches no less than when a gland secretes. It is not too much to say that when we are moved to tears or laughter it is chemical reactions that are the underlying causes to which ultimate analysis must lead us." Who can doubt it who has seen the effects of drugs or other chemical bodies on the moral and intellectual faculties or other manifestations of the nervous system. In myxœdema, cretinism, alcoholism, for instance, is it not fantastical to imagine that a material drug can effect a spiritual essence? Poets make much of the paragon perfection of man and argue therefrom his supernatural attributes, but we know from our daily work that man at the present stage of evolution is frequently fearfully and wonderfully badly made—that many specimens are never out of the repair shop. It is probable that in this society there is not a member who has a perfect pair of eyes or whose nasal septum is not out of the perpendicular. In the highest and most important function for the perpetuation of the race (that of reproduction) the complaint that is continually poured into our ears is that of inefficiency.

The question of diet bulks largely in any scheme of treatment. Perhaps the burning question of the hour is what amount of proteid is necessary and advisable to maintain a high standard of health? The question cannot be answered with any certainty at present but we know by direct experiment under different conditions, as well as by the habits of some hardy and intellectual races, that great physical and intellectual activity is compatible with much less than the conventional dietary of 100 grammes or more of proteid, and that particularly in persons whose ancestors have for generations taxed to exhaustion point the cells concerned in nitrogenous metabolism a great part of this proteid may be advantageously replaced by carbohydrates or other non-nitrogenous foodstuffs, the more especially because much of the proteid never reaches the tissues as proteid. He is a wise man who knows his own metabolic limitations and does not attempt to emulate men with primitive digestions. With new drugs and new remedies we are apt to forget the debt we owe our medical forefathers who by sheer therapeutic intuition discovered and handed down to us such valuable remedies as opium, cinchona bark, mercury, nuxvomica, vaccine, and coca leaves, which the Mexicans used for generations as a local anæsthetic before the alkaloid was discovered. Coal tar was the forerunner of, and used for the same purposes as, carbolic acid. Carbolic acid gave birth to salicylic acid. The pine-forest cure suggested eucalyptus oil. I have to confess to a sneaking affection for the old-fashioned, much-ridiculed blunderbuss prescription. Each tissue knows its own requirements. It may be that I was prejudiced in the favour of these prescriptions in my early apprenticeship days. But, after all, complexity is a higher stage of evolution than simplicity. And nature's remedies

are all complex. Take, for instance, the natural mineral waters, or opium or cinchona. They are all blunderbuss prescriptions. Even the simplest fare, such as bread-and-milk, contains over 20 ingredients and yet each individual ingredient is unerringly conducted to its affinitive tissue.

We may hope that as pharmacology advances that mechanical or empirical prescribing will become less and less frequent. At present we know that drugs produce their effects either by chemical combination or by their physical properties interfering with oxidation processes, as sand puts out a fire, and their ability to penetrate a cell may depend upon the size of the molecules of which they are composed. Instances of chemical combination are shown in the exhibition of alkalies in diabetic coma and sulphonal poisoning, in the action of sulphate of soda in carbolic acid poisoning, and of sodium hyposulphite in combining with prussic acid to form the non-poisonous sulphocyanide. The most powerful narcotic substances are those which combine a very slight solubility in water with a very high solubility in ether, olive oil, or brain lipid. The cerebral cells are more sensitive to alterations in their composition than other cells and they contain a much larger percentage of "lipoid matter" or fat, so that these drugs tend to accumulate in them. Here we have an instance of the physical action of remedies. To this class belong the trional group. As a practical point I may remind you that the effects produced by adrenalin upon any tissue are such as follows excitation of the sympathetic nerve which supplies the tissue. Consequently, in cases of hæmorrhage from the lungs it is contra-indicated, because the muscles of the pulmonary blood-vessels are not supplied with constrictor fibres.

And now, Gentlemen, in conclusion, I fear that the limits of your patience must be reached. I am only too conscious of having rushed you from China to Peru, and only hope that on the voyage you may have annexed here and there some trifling *bric-a-brac* to furnish your study. The late Dr. Abercrombie sums up the lesson that I would take to myself and offer to you this evening. He says: "In regard to the effect of medicines in particular, there are two opposite errors to be equally avoided—namely, an implicit confidence in the power of particular remedies in every case, and a total scepticism in regard to the resources of medicine. Both these extremes are equally unworthy of persons of calm philosophical observation, and they who advance carefully in the middle course, not misled by the temptation to hasty conclusion, and cautioned, but not discouraged, by the danger of concluding falsely, are most likely to contribute something towards diminishing the uncertainty of medicine."

ON OPSONINS AND TREATMENT BY BACTERIAL VACCINES.¹

By J. L. BUNOH, M.D., D.Sc. LOND., M.R.O.P. LOND.,
LATE RESEARCH SCHOLAR OF THE BRITISH MEDICAL ASSOCIATION.

THE advances of science, like those of nature, are slow, and the marvellous discoveries which are introduced to the public in their completed form and then appear, like Pallas Athene, to have leapt fully developed from the head of their creator, can on closer examination be traced through all the stages of their gradual development. Although, to the romantic imagination, the falling of an apple, the swinging of a church lamp, and the flowing of water from a bath revealed to Newton, to Galileo, and to Archimedes respectively the secrets of nature, nevertheless, truth compels us to recognise that these secrets were only unravelled by ceaseless striving and strenuous work, and that only by similar means can future advances in the field of research be accomplished. Thus we can trace back to far distant times the first attempts at preventive inoculation. It was early recognised that certain diseases occur only once in the life of the individual and he is in future protected against attacks of the same disease. From this it was a short step to the artificial production of such diseases and it has been stated that the practice of artificially inoculating small-pox

¹ A paper read before the Medical Society of University College, London, on Nov. 14th, 1906.

from time to time shows considerable variations. From the point of view of diagnosis, where tubercle bacilli cannot be found in the sputum, such a series of observations showing the presence or absence of periodic variations in the index is of the greatest importance and may be the means of the disease being arrested and the patient cured before the bacterial infection has assumed serious proportions. In other words, we may by this means be able to make an earlier diagnosis than would otherwise be possible and send the patient to a sanatorium in time to effect a rapid cure. Some observers think, however (and I agree with them), that a low index may precede infection, and even be the cause of infection, owing to an inborn or acquired inability to manufacture a sufficient quantity of protective material. From the point of view of prognosis a low index necessitates a very guarded prognosis, either as regards the possibility of infection or the relapse of a so-called sanatorium cure. Bulloch examined 14 picked cases of such cures and found their resistance low in every case except one, and of these cases one, which was considered a perfect cure, relapsed within a year.

An index appreciably above normal means, as a rule, that infection has already taken place, especially if repeated estimations show considerable fluctuations of the opsonic index. Bulloch estimated the opsonic index in 44 healthy medical students and 40 healthy hospital nurses, and for the 44 individuals he got an average index of 0.96. The variations in health range from 0.8 to 1.2. A phthisical patient, however, may have an index considerably more abnormal than this. It may be more than 50 per cent. below, or more than 100 per cent. above, normal and, in addition, the patient's index to staphylococci, streptococci, or pneumococci, or even to all three, may at the same time be quite abnormal. In such a case there is, of course, a mixed infection. In acute recent cases the index to tubercle is generally low, whether it be a lesion of the lungs, joints, or skin, because the focus of disease has not been shut off by fibrous or granulosomatous tissue and toxic material is absorbed at varying intervals into the circulation and negative phase succeeds negative phase or becomes superimposed on preceding negative phase. Where the immune body is deficient, the patient's general health bad, and resisting power low the index is low, and a very small amount of tuberculous toxin is sufficient to produce a marked depression of the opsonic index. If, however, the tuberculous lesion is of old standing and has to a large extent become isolated by fibrous tissue and shut off, as it were, outside the organism the opsonic index may be considerably above the normal. In such a case the doses of toxin which enters the circulation are small, and after each such auto-inoculation the resulting negative phase has time to be succeeded by a positive phase. In fact, the patient's protective mechanism is working under fairly satisfactory conditions and if it can only be stimulated to produce sufficient opsonins the tubercle bacillus may be worsted and a cure of the patient effected. But it is essential for success that the auto-inoculations shall be properly spaced and shall not succeed one another before the negative phase which succeeds each inoculation has passed off. When the bacterial infection is localised, as in chronic lupus and many cases of boils and abscess, little if any auto-inoculation occurs and there is no constitutional disturbance due to the microbe, so that in such cases most excellent results can be obtained by means of vaccines. In addition to such injections the patient's general health must be improved and the conditions which have rendered him liable to infection removed so far as possible, so as to increase the natural as well as the artificial immunity brought about by the inoculations.

But tubercle of the lungs is in a different category. One has known so many of these cases lose ground, even when treated early and under the most favourable hygienic conditions in Swiss health resorts and elsewhere, because they are inoculating themselves from their pulmonary lesion and from carelessness and inattention to details these auto-inoculations are allowed to succeed one another too rapidly, causing superposition of negative on negative phase. The constitutional disturbance which results from such a localised bacterial infection of the lungs shows itself in pyrexia, weakness, and anemia, and when the tuberculous infection is accompanied (as is usually the case in phthisis) by streptococci, staphylococci, or pneumococcal infection these symptoms are still more marked. Such a patient should be placed at rest in a pure atmosphere as free as possible from germs and under the best obtainable external conditions until his lung mischief has quieted down and

auto-inoculations have so far as possible ceased and his opsonic index become fairly constant. Small doses of tuberculin may then be injected and the effect on his opsonic index estimated, at first frequently and afterwards at such intervals as will enable the duration and degree of the negative and positive phase caused by each injection to be known, having regard also to the possibility of intercurrent auto-inoculations, each of which would, of course, until its effect had passed off, prohibit the injection of tuberculin. Where it is possible to determine the nature of a mixed infection, vaccines prepared from the organism which is associated with the tubercle bacillus in the patient should be employed.

Tuberculous affections, in which surgical treatment is necessary, can be considerably benefited by simultaneous injections with tuberculin. Through the kindness especially of Mr. R. J. Godlee, of Mr. B. Pollard, and of Mr. R. Johnson, I have been able to watch the effect of such treatment in some of their cases in University College Hospital and I take this opportunity of thanking them most cordially. It must be remembered that the effect of a surgical operation on a tuberculous focus is to throw some of the toxin into the circulation and so depress the resistance of the individual. This negative phase is necessarily disadvantageous to the patient, even if it does not directly interfere with the healing of his wound, or, coinciding with an accidental auto-inoculation of the patient, lead to general tuberculosis. If, however, the opsonic index be raised before operation by suitable injections of tuberculin, the negative phase due to the operation becomes superimposed on a positive phase produced by artificial inoculation and its injurious effects are masked. Tuberculin administered after operation may not only assist in the immediate recovery of the patient but may also help to prevent recurrence of the disease, especially if it has been found impracticable to remove every tuberculous focus. Such injections must, of course, be kept up over a considerable period of time.

I should like to refer briefly to two cases of Mr. Godlee's which were operated on in January, 1906, and have given excellent results. The first was a woman, aged 34 years, living in the country who had lupus of the left cheek for 26 years. She had been under treatment at a skin hospital for two and a half years and had had about 600 exposures to x rays as well as much other treatment without curing the lupus. When she came under Mr. Godlee's care she had a patch of lupus about three inches long by two inches broad, superficially ulcerated and merging into scar tissue about an inch wide at the lower edge. There was a small outlying nodule on the left ala nasi. Brown pigmentation and dilated venules were present on the side of the face and lips as a result of the x rays. On Jan. 23rd her opsonic index was 0.58. She was given an injection of 1/100th milligramme of tuberculin. On Jan. 31st her opsonic index was 0.76, and on this date she was operated on by Mr. Godlee. An incision was made all round the affected area of the skin and the included area dissected off the deeper structures. Bleeding was stopped by torsion, hot water, and adrenalin. The raw surface was covered in by Thiersch grafts cut from the front and inner side of the right thigh. On Feb. 1st her opsonic index had fallen to 0.62 and on the 7th she was given a second injection of tuberculin and again on the 13th and 20th. On the 27th the skin graft had completely taken and she left the hospital for her home in the country. Since then she has attended at the hospital from time to time and has had four more injections of tuberculin, the last dose of 1/100th milligramme on Sept. 11th, when her opsonic index was 0.94. There was no recurrence of the lupus.

The second case was that of a man, aged 38 years, who had already had one tuberculous testicle removed and was admitted under Mr. Godlee's care to have the second testicle removed and a tuberculous ulcer of the tongue excised. This was done on Jan. 31st, 1906. In the skin of the arms and trunk were the scars of nodules (presumably tuberculous) which had already been cut out. Before operation his opsonic index was 0.62 and the day after operation it was 0.51. On Feb. 5th it was 0.58, and on the 7th he had an injection of 1/100th milligramme of tuberculin, which was repeated three times during his stay in hospital, his opsonic index on March 7th being 1.1. This gradually dropped to 0.83 on July 31st, when he came to London and was given an injection of 1/100th milligramme. He writes that he is feeling well, is at work, and has had no recurrence since leaving the hospital.

bacilli, and, by washing, removing the extracellular toxins which chiefly constitute the "old" tuberculin. The residue is then made into an emulsion with distilled water after trituration, centrifugalised, and the supernatant fluid pipetted off. To it 20 per cent. of glycerine is added to preserve it and it is standardised so that one cubic centimetre contains ten milligrammes of solid substance. Dilutions can then be made to any required dose and these are heated for an hour at 60° C. in capsules so as to kill any possibly contained living bacilli. The dose is to commence with seldom more than $\frac{1}{100}$ th milligramme, usually less, and is injected subcutaneously with strict aseptic precautions. The injection should cause no rise of temperature and no general or appreciable local reaction. The amount of the dose given at subsequent injections and the intervals between the doses depend on the influence produced by the preceding dose on the opsonic index to tubercle, but the doses of one-half, one, or two milligrammes which were formerly given, are now never employed. Tuberculins have also been prepared by other pathologists, by modifications of the methods given above, or by employing hydraulic pressure to cultures of tubercle, or by oxidising them with hydrogen peroxide so as to convert the toxins into antitoxins. But the tuberculins of Hahn, of Denys, of Béraneck, of Buchner (known as tuberculo-plasmin), of Landmann (known as tuberculol), of Hirschfelder (known as oxytuberculin), and of Klebs (known as tuberculooidin and anti-phthisin) are seldom used in this country.

The elaboration of protective substances in the organism can be induced by chemical substances or vaccines prepared from bacteria other than the tubercle bacillus. I myself have used and injected vaccines of pneumococci, streptococci, and the various forms of staphylococci during the past 18 months. These vaccines are emulsions of that species of organism which has produced the disease in the patient and, inasmuch as different strains of the same organism differ greatly, the vaccine should, when possible, be prepared from a pure culture of that particular organism grown directly from the lesion to which it has given rise in the patient. In some diseases this can be done only with difficulty. In pneumonia, for instance, a mouse must be inoculated from the patient's sputum or empyema pus and a pure culture of the pneumococcus obtained from the mouse's heart blood, and a vaccine made from the culture. The emulsion prepared from such a culture must be centrifugalised and standardised so that a certain volume contains the dead bodies of a certain known number of bacteria, plus their products of metabolism. The initial dose must always be small since patients react very differently to injections and it is essential not to induce too marked or too prolonged a negative phase. This is true of any injection of a vaccine, whether it be the first or a subsequent one, but the reaction of any particular patient to a certain vaccine can be gauged from the alteration of his opsonic index after the first dose.

The inoculation of a vaccine is followed always by a certain definite train of events which, according to Wright, is as follows: 1. Upon the inoculation of a vaccine there supervenes a period of intoxication which is characterised by a decline in the anti-bacterial power of the blood. This "negative phase" is more or less accentuated and prolonged according as a larger or smaller dose of the vaccine is inoculated. In the former case the "negative phase" may disclose itself to clinical observation by a temperature reaction and constitutional disturbance. In the latter case the "negative phase" may be quite unaccompanied by clinical symptoms. 2. Upon the "negative phase" there follows a "positive phase." This phase, the characteristic feature of which is an increase in the anti-bacterial power of the blood, corresponds to a period of increased resistance. A curve which shows graphically the changes in the anti-bacterial power of the blood runs up in many cases to a sharp peak and sinks away first comparatively rapidly and afterwards more slowly. There are associated in many cases with the climax of the "positive phase" a sense of increased physical vigour and a very pronounced feeling of well-being. 3. After the negative and positive phase the blood may be maintained for a variable period (after tubercle inoculations occasionally for as long as a month) at a somewhat higher level of anti-bacterial power than before inoculation. Or—and this in connexion with inoculations of tubercle vaccine is a more usual event—the anti-bacterial power of the blood may over and over again fall back after ten days or a fortnight to the level at which it stood anterior to the inoculation.

If the right dose has been given the negative phase will not be too marked or unduly prolonged and will soon be followed by a well-marked positive phase, and in succeeding inoculations the negative phase will be still less. But if too large a dose be given or it be injected when the index is falling the positive phase will make its appearance very late or not at all. I purposely lay stress on this point because some of the first injections which I gave more than 18 months ago were too large, and I have known an injection of $\frac{1}{10}$ th or $\frac{1}{20}$ th milligramme to be followed by a negative phase which was so marked as to last for weeks. It seems to be generally agreed that only the minimal dose must be employed which will produce a satisfactory response and this must not be increased until it ceases to produce its effect. The dose, moreover, must not be repeated until the effect of the preceding dose is passing off. If it were possible to produce a summation of positive phases it would be advantageous to give successive doses at short intervals, so as to produce a maximal favourable effect, but such summation is not possible in the case of tubercle. Each inoculation, therefore, produces its effect independently, and it remains to take the greatest advantage possible of the increased elaboration of protective substances which the artificial stimulus has produced. It is obvious that this can only be done by bringing the protective substance as closely as possible into contact with the bacteria which are the cause of the disease. This is simple enough when the bacteria lie within easy access of the blood stream, but when they are flourishing in the tissues in circumstances most favourable to their growth, remote from the blood stream and in contact only with a lymph which is naturally poor in anti-bacterial substances, the mere increase of the opsonic power of the blood is not sufficient. The opsonin must be brought into direct action with the bacilli in the diseased focus, and this can only be done by increasing the lymph flow through that focus. When it is situated near the surface this may best be brought about by the application of counter-irritants, rubefacients or heat, either dry or moist, in the form of hot-water bottles, hot-water tins, or the commonly used hot boracic fomentations. When the focus or disease is in a joint Bier's method of passive congestion, used with so much success in this hospital by Mr. A. E. J. Barker, is one of the greatest service. The effusion of lymph produced by each of these methods is very considerable, and, in addition, the viscosity and coagulability of the blood can be greatly diminished by the internal administration of decalcifying agents, such as citric acid. The diseased tissues can thus be irrigated by an increased flow of lymph, and if this lymph contains an amount of protective substance which has been artificially increased by means of vaccines the fight against the disease germs is carried out under conditions which are much more likely to lead to their destruction. In some cases the surgeon can render the greatest assistance by operative removal of part or the whole of the diseased focus. It is, however, to be borne in mind that in the case of abscesses cure is not brought about merely by the evacuation of the pus and the bacteria contained in it, but rather by opening up the channels which have been closed by the pressure and the vessels which have been blocked, so as to re-establish the stream of blood and lymph containing protective and anti-bacterial substances. That these are normally wanting in the pus of an abscess can easily be shown by centrifuging the fluid and proving that the liquid portion contains no opsonin. Apart from artificial increase of protective substance by injections of vaccines we must always remember the possibility of a similar increase by means of auto-inoculation, but localised bacterial infections give rise to them very scantily or not at all. Such infections run a chronic course over long periods of time, and do not tend to get well. In such cases the protective substance, if it is to be increased at all, must be increased artificially.

The opsonic index having been determined, it remains to deduce from this some conclusions as to the patient's state. If the case be one of suspected tubercle and the opsonic index to tubercle be as much as 30 per cent. above or below normal, a positive diagnosis may be made. An index to tubercle below 0.8 is undoubtedly abnormal and indicates either a strong disposition to infection such as is to be expected in a member of a family several of whom have already shown signs of pulmonary tuberculosis, or that infection has already taken place. There is not sufficient evidence to show whether the low index is necessarily the result of infection in any particular case, but this is probable if the index determined

which proved to be altered blood. The main mass of the splenic substance formed the outer and part of the posterior walls of the cyst, was about four inches long, and roughly maintained the shape of the normal spleen. Another good-sized mass of splenic substance was situated on the inner wall near the hilum, and between these two a broad bar of it extended transversely, roughly dividing the cyst into two nearly equal compartments, an upper and a lower. The splenic substance was much tougher than normal. The wall of the cyst varied from about one-eighth to one quarter of an inch in thickness; in some places it appeared to be composed of fibrous tissue only, in others splenic substance could be seen inclosed in the fibrous tissue. The inner surface of the wall was rough and coated with remains of blood clot, whilst on the peritoneal surface were remains of adhesions, torn through in removal. The main trunk of the splenic artery was found entering at the hilum; it was somewhat thickened, but not markedly so. Fine probes were passed into the main artery, which traversed the transverse bar of splenic substance mentioned above, but all attempts to discover a branch communicating with the interior of the cyst were unsuccessful.

The accompanying illustration (Fig. 1) shows the organ

FIG. 1.

The cyst viewed from the front. The two compartments are well shown; a pad of wool has been inserted into the lower one to prevent it collapsing while being photographed.

viewed from the front and the cyst opened by a transverse cut. The remains of the spleen are seen on the right of the figure and a probe enters the splenic artery on the left at the hilum, to emerge in the spleen substance where the artery divides into several branches. The two compartments of the cyst are well shown.

Microscopical examination.—Sections of the spleen showed great thickening of its peritoneal coat. The spleen substance proper was divided from the cavity of the cyst by a fibrous tissue coat, of less density than that on the peritoneal surface, which merged into the remains of blood clot everywhere lining the cavity of the cyst; no limiting layer of cells was present. The substance of the spleen showed a slight but distinct fine fibrosis. The Malpighian bodies were well developed and quite unaffected by the fibrosis. A large amount of pigment (which gave the reaction for free iron) was scattered throughout the section. The cells contained in the trabeculae differed from the normal only in the higher proportion of polymorphonuclear neutrophils to lymphocytes and in the markedly increased number of coarsely granular eosinophile cells, the latter forming a striking feature of sections stained by Leishman's method. Sections stained with methyl violet showed slight amyloid degeneration in the trabeculae throughout the spleen substance, Malpighian bodies being unaffected. In the

thicker parts of the cyst wall (see Fig. 2) three distinct layers were present—an outer fibro-muscular layer, an inner fibrous lining of more open texture merging into the altered blood clot, and a middle zone consisting of remains of splenic tissue undergoing fibrosis. In the inner layer a good deal of pigment, some of which gave the reaction for free iron, was present. There was no sign of any layer of

FIG. 2.

A portion of the cyst wall where the three layers are well defined: (a) outer fibro-muscular layer; (b) middle layer of spleen pulp; (c) inner fibrous layer, and (d) blood clot forming lining of cyst. (1 in. obj. B eye-piece.)

cells lining the cyst cavity. The middle layer resembled the spleen, as described above, but the fibrosis and increased proportion of coarsely granular eosinophile cells were more marked. In the splenic artery there was slight patchy thickening of the intima in the portions prepared for microscopy, but there were no large patches of degeneration and no interruption of continuity of the endothelium. No amyloid degeneration could be detected. There was advanced cirrhosis of the liver of the polylobular type with well-marked perihepatitis, bands of fibrous tissue extending downwards from the thickened capsule into the liver substance. The interstitial fibrous tissue was extensively infiltrated with round cells, of which the polymorphonuclear neutrophils formed by far the larger proportion. Fatty change in, and necrosis of, the liver cells were very marked and in some areas the liver cells had broken down into masses of debris, these latter changes being evidently the result of the septic infection from the suppurating aneurysm. All the vessels in the liver showed well marked amyloid degeneration. In the kidney the usual changes of chronic interstitial nephritis were well marked and in addition there was amyloid degeneration in the vessels and glomeruli. The interstitial tissue was very cellular and here, too, the high proportion of polymorphonuclear neutrophile cells was noticeable. All the vessels showed well-marked thickening.

Non-parasitic cysts of the spleen are of extreme rarity and in text-books of pathology are dismissed with a bare reference to their existence. The Hunterian Museum of the Royal College of Surgeons of England contains one specimen of a hæmorrhagic cyst from the human subject and one of a serous cyst in the spleen of an ox. Attention was first drawn to the condition by Antral in 1829, and since then some 32 cases observed during life and about 20 met with accidentally at necropsy have been recorded.

Heinricius¹ has collected all recorded cases up to 1904, and discusses fully the various theories which have been put forward to explain the formation of these cysts; whilst lately Powers² has added some further cases. Two classes of cyst formation are discussed by Heinricius with illustrative cases: (c) serous cysts, usually multiple and of small size, which are considered to arise either from dilatation of

² Powers: Annals of Surgery, 1906, part civl.

A case of Mr. Pollard's is also of interest in that the tuberculous affection was acute when the patient came under his care.

A girl, aged 11 years, was admitted to University College Hospital on May 18th, 1906, and discharged on June 27th cured. Three years ago she was seen in the out-patient department by Mr. Pollard for signs of tuberculous disease of the left hip. She was put on a Thomas double hip splint and remained on it for a year. The symptoms gradually subsided and the disease appeared to have cleared up. She was kept lying down for another six months, then she was up and about. Since then, during the last six months, she had several bad falls and the mother attributed the present condition to these falls. When admitted the right hip was greatly swollen and there was a large abscess on the anterior and outer parts of the joint. The skin over the abscess was slightly red. The hip joint was quite fixed in good position, the limb being slightly abducted and rotated out. There was some tilting down of the pelvis on the right side with one and a half inches apparent lengthening, but in reality half an inch shortening. There was no sign of disease in any other joint or organ. On May 19th Mr. Pollard operated by the usual incision for an anterior excision of the hip. The acetabulum was found to be perforated and an abscess inside the pelvis was evacuated, the diseased bone scraped and a counter opening made at the lower part of the abscess and two tubes inserted. She suffered considerably from shock. On admission the patient's temperature was 100.6°F . but after the operation it did not rise above 100.2° . Seven days after the operation she was given an injection of $\frac{1}{100}$ th milligramme tuberculin T.R. Next day her highest temperature was 99.2° but after that it did not rise above 99° . Six days after this injection and 13 after the operation, a second injection of $\frac{1}{100}$ th milligramme tuberculin was given, and again a third dose on June 22nd, her temperature now being normal, her appetite good, and only small granulating surfaces present where the tubes had been. On June 27th she left the hospital and went to the seaside, her opsonic index then being 1.1 as compared with 0.68 when first examined. From there she came to the hospital at the beginning of August and was given a further dose of $\frac{1}{100}$ th milligramme tuberculin. On Sept 24th her opsonic index was 0.92 and she is apparently quite cured.

My thanks are due to Mr. P. M. Heath, surgical registrar, for the clinical notes of these cases.

It is, of course, possible that these cases might have done as well without tuberculin, but their past history was in each case unfavourable and showed a tendency to recurrence, while their power of resistance to the tubercle bacillus was low. This was increased by tuberculin injections, and it is reasonable to suppose that their rapid recovery was at least aided by increasing their resisting power to the bacterial infection. I will not weary you with any more cases, but I might refer you to a paper in THE LANCET of Oct. 27th, 1906, p. 1130, by Turton and Parkin of Hull giving details of 34 cases of various kinds which they have recently treated in their practice, in 30 of which the injection of bacterial vaccines gave excellent results. The results of treatment of some dermatological cases have already appeared in a paper by Pernet and myself in the October, November, and December numbers for 1906 of the *British Journal of Dermatology*. So many other successful cases have now been recorded that the employment of bacterial vaccines must in the future prove of the greatest service in the treatment of disease when controlled by the method, which Wright and Douglas have so ably elaborated. They must in many cases be used in conjunction with other methods, for as long as a patient has a focus of disease he is liable to reinfection. In conclusion, I have to express my indebtedness to Dr. W. Bulloch for much valuable advice and assistance and to Professor Sidney H. O. Martin for his kindly encouragement and for permitting me to avail myself of the resources of his laboratory.

Park street, Grosvenor-square, W.

A CASE OF HÆMORRHAGIC CYST OF THE SPLEEN.

By W. L. HARNETT, M.A., M.B. CAMB., F.R.C.S. ENG.,
ASSISTANT PATHOLOGIST AND DEMONSTRATOR OF MORBID ANATOMY,
ST. THOMAS'S HOSPITAL.

THE patient, a male, aged 40 years, was admitted into St. Thomas's Hospital under the care of Mr. Clutton on Nov. 25th, 1905. He was at that time a coal porter, but had been in the Marines for 21 years and had served abroad in various parts of the world for, in all, 15 years. There was a clear history of malaria, but he denied having ever had syphilis. The family history was of no interest. Seven weeks previously to admission he noticed a small swelling on the inside of the left thigh just above the knee. This increased in size so rapidly that in less than a month he was unable to walk. On admission a pulsating swelling, having all the characters of an aneurysm of the popliteal artery, was present on the inner side of the left thigh just above the knee. The leg was markedly wasted and, in common with the rest of the body, was covered with a pustular rash of a scabetic character which, according to the patient's statement, had been present for some time. There was well-marked general arterio-sclerosis and no pulsation could be felt in the peripheral arteries below the aneurysm. The liver and spleen could be felt to be enlarged. The urine contained a trace of albumin. During the few days preceding operation the aneurysm increased rapidly in size, the circumference of the thigh, which on admission was $14\frac{1}{2}$ inches, rising to $15\frac{1}{2}$ inches three days later. At the same time the skin over the aneurysm began to show signs of pressure. On Nov. 28th Mr. Clutton operated and ligatured the femoral in Hunter's canal, the walls of the artery being found to be extensively diseased. During the next few days the temperature assumed a septic type, with signs of suppuration in the neighbourhood of the aneurysmal sac, and at the same time suppuration became more active in the pustules on that leg. There were no signs of gangrene in the leg, the state of the circulation being as before the operation. On Dec. 3rd an incision was made over the sac without actually opening the latter and extensive cellulitis was found. As will be detailed below, suppuration had actually taken place in the sac, the infection having presumably reached it from the pustules in the overlying skin, the ligation having probably hastened events by diminishing the blood-supply to the parts. After the incision the temperature fell but death took place two days later.

Post-mortem examination.—Only a partial necropsy was allowed. The skin over the aneurysm was in a sloughing condition and the sac was found to be filled with suppurating blood clot. The femoral and popliteal arteries were in a state of advanced atheroma with extensive calcification. The lumen of the femoral was firmly occluded by the ligature. The heart was enlarged, mainly owing to hypertrophy of the wall of the left ventricle. Both mitral and aortic valves were thickened, but were competent when tested in the usual manner; there were no recent vegetations upon any of the valves. There was well-marked atheroma of the aorta, though not so extensive as might have been expected from the condition of the femoral and popliteal arteries. The peritoneum and intestines were normal. The liver was enlarged, weighing $8\frac{1}{2}$ ounces, and was pale in colour and markedly cirrhotic. In addition, there were several deep puckered scars, resembling those caused by the healing of gummata. The cut surface showed the fibrous tissue to be increased, dividing up the parenchyma into islets in the manner usual in polylobular cirrhosis. There was slight enlargement of the kidneys, the organs weighing $7\frac{1}{2}$ and 7 ounces respectively. The capsules were adherent and on stripping them a coarsely granular surface of an unusual appearance was left, the elevated areas being of a dead white colour, in striking contrast to the darker coloured depressed portions. The amount of cortical substance was relatively diminished and was of a white colour, whilst the pyramids were dark. The renal arterioles were moderately thickened. The spleen was converted into an enormous unilocular cyst, measuring about 10 inches by 6 inches, of a dark indigo colour, with an irregular bossy surface. There were numerous adhesions, of considerable standing, between the peritoneal surface and the surrounding organs. On section the cyst was found to contain nearly a pint of dark, brownish-red, turbid fluid.

LITERARY INTELLIGENCE—Mr. James Stanley Little, from whose pen we publish this week an interesting lay view upon the Riviera as a health resort, is publishing through Messrs W. H. and L. Collingridge a new work entitled "The Doom of Western Civilisation." Mr. Little's title is probably more pessimistic than his book, for his previous writings lead us to believe that he thinks a good deal of vitality still remains in the British Empire.

lymph vessels or from inclusions of peritoneal endothelium; and (b) hæmorrhagic and sero-sanguineous cysts, single and usually of considerable size, which he, in common with other observers, regards as being due to the rupture of an intrasplenic vessel with subsequent encapsulation of the extravasated blood. Powers further differentiates two varieties of this latter class: one form originates in a subcapsular hæmorrhage, slight but continuing for a long time, the peritoneal capsule undergoing a low form of inflammation with the formation of adhesions and the spleen being liable to atrophy from the pressure of the cyst; whilst in the second form the hæmorrhage takes place deep in the parenchyma and the walls are formed of normal splenic tissue, which in time becomes transformed into fibrous tissue, the cyst tending as it enlarges to approach the surface. That the present specimen belongs to this variety of Class (b) is evident from the large masses of nearly normal splenic tissue contained in the walls of the cyst (as described above).

This case is described in detail as it presents many points which support the view that these cysts arise from rupture of an intrasplenic vessel. The patient was the subject of advanced arterial disease and had a popliteal aneurysm, together with evidence of syphilis in the form of gummatous cirrhosis of the liver and amyloid disease in the viscera. It is possible that there may have been a small aneurysm of one of the branches of the splenic artery, from the rupture of which the hæmorrhage originated, though the absence of any marked disease of the main splenic artery is rather against this. No communication between any of the arterial branches and the interior of the cyst could be discovered, but one cannot lay any stress on this point, as the hæmorrhage would almost certainly proceed from a small perforation, and would probably take the form of repeated small hæmorrhages spread over a long period of time. There was a history of malaria in this case, and in many of the cases quoted by Heinrichs mention is made of this point. When present it is an important etiological factor, as the liability of the enlarged malarial spleen to be ruptured by trivial injuries is well-known. And when to this predisposition is added atheromatous and amyloid disease of the vessels it is obvious that very slight causes might bring about the extravasation of blood. In some of the cases there was a definite history of trauma, but these were a minority. As regards the anatomical site of the leaking vessel in this case it was probably close to the hilum since the main mass of unaltered spleen substance formed the left-hand wall of the cyst.

In the two papers referred to the questions of symptoms, diagnosis, and treatment are considered, but these I do not propose to enter into here, as they did not come up for discussion in this case, the existence of the cyst being only discovered at the necropsy. The interest of the case lies in the presence of coincident factors which clearly indicate the pathology of one form of this rare condition.

I have to thank Mr. Olnton for permission to make use of the clinical notes of the case.

THE RELATIVE SIZES OF THE MATERNAL PELVIS AND OF THE FÆTUS IN EUROPEANS, EURASIANS, EAST INDIANS, AND BENGALIS.

By J. C. HOLDICH LEICESTER, M.D., B.S., B.Sc.
LOND., M.R.C.P. LOND., F.R.O.S. ENG.,
CAPTAIN, I.M.S.; FIRST SURGEON TO THE GENERAL HOSPITAL,
CALCUTTA.

SOME time ago there appeared in THE LANCET¹ an interesting and suggestive paper by Captain Clayton A. Lane, I.M.S., entitled "A Clinical Comparison of the Maternal Pelvis and of the Fœtus in Europeans, Eurasians, and Bengalis," in which he tabulated the full measurements of 118 pelvises, the weights of 357 children, and the measurements of the heads of 158 children, and from the results obtained he enunciated a law that: "The child grows in utero in such a manner, and at such a rate that at full term his size is proportional to that of the mother's pelvis through which he has to pass in order to be born." At a later date a leading article on this paper appeared in the same journal.² At the time of

reading these articles I was holding the post of surgeon to the Eden Hospital for Women, Calcutta, thought that as I was in such a favourable position to work it would be both interesting and instructive to carry out a further course of investigations on the lines, but which should embrace a far larger series. I began this work in October, 1903, and with the exception of a few weeks' break in April and May, 1904 (due to ill health) I continued it until I relinquished my appointment in 1905. I endeavoured to adopt as far as possible exact same methods of weighing and measuring the children of measuring the pelvis, as were employed by Lane and

² THE LANCET, Oct. 3rd, 1903, p. 953.

and interspinous measurements bear no relation to the length of the conjugate diameter is again demonstrated. The differences between the intercrystal and interspinous diameters are, on the whole, slightly more marked, but whereas in his table he found that as the conjugate diameter increased in size, the percentage of the interspinous to the intercrystal diameter showed a regular successive diminution, my results fail entirely to demonstrate anything of the sort. This remark applies to the measurements of all the different races equally. As none of the figures in my table show any regularity in this respect it would appear probable that it was merely a coincidence that those cases measured by Lane showed this striking regularity of diminution. This particular point seems to me of itself of little importance as these numbers, as he himself mentions, are of no clinical value in any given case; for in any given size of conjugate diameter it will be seen that the interspinous and intercrystal measurements vary both actually and relatively within even wider limits than in his tables. It will also be noted that with the highest conjugate diameters this average percentage tends to increase rather than to diminish. In Table II. practically the same facts are brought out as in Lane's corresponding table (III.), except that even greater differences are to be found between the maximum and minimum measurements; but this is exactly what would be expected as the result of the larger number of cases measured.

Turning next to Table III., and comparing this with his corresponding table (IV.), whereas he found that the average measurements of the East Indian pelvis were even smaller than those of the Bengali, and, moreover, that the shape of the false pelvis was in them not that of the Bengali, it will be noted that in my table so far from the pelvis of East Indians being smaller, it is on the average larger and the false pelvis is shown to be practically of the same shape; and, furthermore, it will be seen that the Bengali pelvis is smallest, the East Indian next in size, the Eurasian third, and the European largest of all; there would thus appear to be a regular gradation of size in proportion to the admixture of the native element, which is certainly what one would have expected rather than the results obtained by Lane. It may further be noted that the average measurements of the Bengali pelvis and of "Other Natives" are so nearly alike that it would seem to be permissible to argue that the size of the East Indian pelvis would be little, if at all, affected by the question as to whether the native element is Bengali or otherwise.

Coming next to the results of the measurements of the child's head as shown in Table IV., my figures on the whole differ very slightly from those obtained by Lane (vide Table V. in his paper); but in comparing Table V. with his corresponding table (VI.), in which he obtains a very remarkable and striking relationship between the size of the child (as gauged by its weight) and the size of the pelvis (as gauged by the conjugate diameter) through which it passes, the weight of the child showing a steady successive rise with the increase in size of the conjugate diameter, my results are not at all so strikingly regular, although they show a tendency in the same direction. This is clearly demonstrated in the chart here given. Comparing Table VI. with his corresponding table (VII.), in which he again obtains a strikingly regular successive increase in the length of the bi-parietal diameter of the child's head, corresponding to the increase in size of the conjugate diameter of the pelvis through which it passed, here again nothing of the sort is demonstrated by the figures obtained by me, though again there is some tendency in the same direction. This once more seems to me to be only what one would expect, for it is but natural that as a general rule a big woman (in whom usually the pelvis is correspondingly large) should have a big child and vice versa.

I have added a further table (VII.) showing the size and weight of the children of various pregnancies passing through pelvis of the same conjugate diameter. I have only tabulated four sizes of pelvis and these only in Bengalis, because they are the only ones in which I have obtained sufficient numbers of measurements to make the results of any value at all. This table shows again how much the measurements of the child's head passing through the same sized pelvis may vary. There is no doubt that its value would have been far greater had it been possible to obtain measurements of successive children of the same mother,

Bengalis are shown by the dotted line; other natives by the "dot and dash" line; East Indians by the interrupted line; Eurasians by the fine continuous line; and Europeans by the thick continuous line.

but as this has not been feasible I thought it would be worth while to tabulate the results here given. In only one instance did I get the measurements of two successive children born of the same mother, and these were as follows:—

	Weight in pounds.	Bi parietal diameter.	Bi mesal diameter.	Suboccipito-bregmatic diameter.	Occipito-frontal diameter.	Maximum vertexo-montal diameter.
First child ...	7.6	3.5	3.0	3.75	4.5	5.125
Second child ...	8.6	3.5	3.0	3.875	4.5	5.0

With the exception of the children born through the pelvis of 3.875 inches diameter, it will be noted that the size of heads of the first children, as gauged by the bi-parietal diameter, are smaller than the succeeding ones and that there is a gradual increase in size in each succeeding pregnancy up to the fifth, after which the heads again begin to get smaller. The weight of the child shows a general tendency in the same direction, but this is not at all so regular as in the case of the bi parietal measurements.

In conclusion, it will be seen that the proportion in weight and size of the child's head to the size of the pelvis through which it is born is by no means so strikingly regular as would appear from the measurements obtained by Lane, and certainly does not in any way seem to justify the enunciation of any law on the subject.

Calcutta.

BRISTOL DISPENSARY.—At the annual meeting of the subscribers of the Bristol Dispensary, held on Jan. 11th, the chairman stated that the committee had decided to appoint an additional medical officer in February; the institution will then have nine medical officers on the staff.

horizontal groove at the base of the mastoid process. The measuring of the other diameters calls for no particular comment. In the case of the pelvis the interspinous diameter was measured by pressing the two thumbs firmly outwards against the anterior superior spines of the ilia and bringing the points of the callipers against the thumbs. The conjugate diameter was measured by sinking the hand in between the two recti abdominis muscles so that the tip of the middle finger was strongly pressed

against the promontory of the sacrum (the patient lying on her back with thighs flexed). The hand was then depressed till its radial edge came in contact with the upper edge of the symphysis pubis, the point of contact being marked off by one of the nails of the other hand. The distance from this point to the tip of the middle finger was then measured off by the callipers. I made, however, two

slight deviations: first, in most cases I checked the measurement of the antero-posterior diameter at the brim, by measuring the diagonal conjugate as well; and, secondly, I endeavoured to record such smaller differences of measurement as one-eighth of an inch. Although, as pointed out in the editorial article on the subject, it is doubtless impossible to measure with absolute accuracy such small differences in the living pelvis without anaesthesia, still I think it may be contended that the results arrived at will, taken as a whole, represent fairly accurate averages. I have also adopted the same classification into Europeans, Eurasians, East Indians, and Bengalis, with the same meaning to these terms—i.e., Europeans, those of pure European extraction with no admixture of any native element; Eurasian, those of mixed European and native extraction in whom the white element predominates; East Indian, those also of mixed extraction.

but in whom the dark blood predominates. I have also further included a class "Other Natives," into which I have put all other native women coming from parts of India other than Bengal. I have excluded other classes, such as Jewesses, &c., as they were not measured in sufficient numbers to give figures of any value. Altogether, during this period 941 pelvis were measured and 699 full-term children were weighed and measured, the measurement, &c., of full-term children, and pelvis of normal women only being recorded.

To compare the results of Table I. (in which for the purpose of economy of space I have combined the measurements shown in Tables I. and II. of Lane's paper) with those obtained by him, as far as these corresponding tables can be compared, his only containing measurements of Bengalis, the well-known fact that the average intercrural

Microscopical appearances of the thyroid and parathyroid glands.—The thyroid presented the well-known features characteristic of myxœdema. There was an almost complete disappearance of gland tissue which had been supplanted by fibrous tissue. Here and there were collections of small round cells and in other places clumps of degenerated thyroid tissue. In these there still remained a suggestion of the normal follicular structure and many of the

FIG. 1.

Parathyroid gland from case of myxœdema (Zeiss A objective). Showing (1) profuse secretion of colloid distending the lymphatics, (2) increase of fibrous tissue breaking up the cells into isolated clumps, and (3) thickened coats of arterioles on extreme right.

altered vesicles inclosed small drops of colloid. The arteries of the gland showed the marked thickening of their coats which has been frequently observed in other cases. The parathyroid glands were compared with those taken from a large number of other subjects and certain points of difference were apparent. The normal gland, it will be remembered, is made up of solid masses of closely packed

FIG. 2.

Another parathyroid from same case (Zeiss D objective). Showing (1) intercellular mesh of connective tissue, (2) much colloid secretion, and (3) tendency of cells to form acinar grouping.

polyhedral cells, the groups being supported by delicate trabeculae of connective tissue. These cells are arranged for the most part without order, but occasionally they show a tendency to group around a common centre and less frequently a completely formed acinus results, the lumen of

which is filled with colloid secretion. The special features wherein the glands from this case of myxœdema appeared to differ from the ordinary glands were: first, in the arrangement of their cells; secondly, in the quantity of their secretion; and thirdly, to a less extent in the stroma and in the walls of the blood-vessels. The arrangement of the cells was unusual owing to the marked tendency they showed to form small vesicles. In contrast to some parathyroids where a more or less prolonged search is required before an example of this acinar arrangement is discovered, in these specimens there were few fields without acini and many fields contained a dozen or more. In each vesicle the epithelium was a layer of cubical cells. The resulting general appearance of the glands was much more suggestive of ordinary thyroid tissue than is usually the case. As regards the features of the individual cells there was no point to be noticed in either nucleus or protoplasm which could not be frequently observed in other parathyroid glands. The colloid secretion was copious. With few exceptions all the vesicles contained this material and drops of it lay between the clumps of unarranged cells. The lymphatics of the gland were distended with the same secretion and on serial section could be traced towards the surface uniting to form large channels which conveyed the colloid away from the gland. After examining some hundreds of parathyroids, in none do I remember

FIG. 3.

A third parathyroid from same case (Zeiss A objective). Showing excessive formation of fibrous tissue whereby a definitely lobular appearance is conferred on the gland.

such vigour of secretion as in these. The slight change mentioned as present in the stroma consisted in some increase of the connective tissue. Certain of the trabeculae were thickened and in parts of the gland there was a delicate intercellular mesh of connective tissue. In one of the glands there was further a slight thickening of the walls of the arterioles. The two fibrous bodies to which reference has already been made proved on section to possess a glandular structure with a fairly advanced condition of fibrosis—less advanced than in the thyroid, more advanced than in the parathyroids. From the remains of the glandular elements it is not easy to decide whether the bodies were originally accessory thyroids or parathyroids, for the details of structure might represent either the one or the other.

In conclusion, it remains to offer an explanation of the changes in the parathyroids. It is not possible, however, in the limits of this paper to discuss the various interpretations that might be set on these changes and I shall content myself with offering what seems to me the correct solution. I do not think that we should regard the changes in the arrangement of the cells and in the amount of secretion as pathological; rather are they to be interpreted as signs of excessive activity of the glands. The particular reason that we advance for this unusual secretion will depend on the view which we take of the physiological importance of the parathyroids—whether we regard them as glands *sub generis* or as glands possessing a true thyroidal function. Accepting

A FATAL CASE OF MYXŒDEMA WITH CHANGES IN THE PARATHYROID GLANDS.¹

By DAVID FORSYTH, M.D. LOND., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO CHARING CROSS HOSPITAL AND TO THE EVELINA HOSPITAL FOR CHILDREN, LONDON.

THE modern treatment of myxœdema has so affected the mortality of the disease that opportunities of examining subjects post mortem are by no means common. While this result is wholly satisfactory to us as clinicians, from a pathological point of view it is, perhaps, regrettable because the work of recent years suggests that the pathogeny of myxœdema is more complex than was at one time believed. The attempted production of the disease in animals has led to results more contradictory than would have been anticipated. The thyroid has been removed and the chronic symptoms of myxœdema have followed; it has been removed and acute nervous symptoms leading to speedy death have resulted; it has been removed with no untoward accident being produced. These results raise a doubt as to whether myxœdema is attributable to the loss of the thyroid function alone, and the doubt is fostered by the fact that in some cases the administration of the gland extract fails in its results. The whole question has been still further complicated by the supposition on the part of many that the parathyroid glands possess a function of prime importance which is intimately bound up with that of the thyroid. To what extent, if any, these small bodies are concerned in the production of myxœdema is not settled; in fact, as far as I am aware, no account of their condition in atrophy of the thyroid has been published.

The particular case which I am bringing to your notice derives its interest not so much from its clinical features as from the post-mortem findings, yet I feel no excuse is needed for submitting it to this purely clinical gathering. The thyroid gland can without exaggeration be looked on as the peculiar property of our Society seeing that its relation to myxœdema was here established. In these circumstances an account of the parathyroid glands will not be without interest. The patient with whom we are concerned was under observation only a short while before death and the notes of her condition are brief. She was admitted into Guy's Hospital under Dr. W. Hale White, and to him I am indebted for access to the clinical report of which the following are the salient points.

The patient, aged 58 years, married, was admitted to hospital on March 19th, 1906, for "general debility." Her father had died from heart disease at the age of 49 years; her mother had lived to the age of 84 years when she died from old age, and in neither was there any history of thyroidal trouble. The patient bore three children, all of whom are alive and well, the eldest being 26 and the youngest 20 years. There is no history of any family hereditary disease. The previous illnesses include none more serious than scarlet fever and German measles in childhood. The outstanding feature of her adult life appears to have been intemperance. The mental state of the patient disabled her from rendering any trustworthy account of her illness and the details were obtained from the husband. By him the disease was dated back four years, beginning insidiously. Even before that date, however, comment had been made on the inactivity of her habits and on her marked disinclination to expose herself to the open air. For three years the progress of the disease was slow, but 12 months ago she was unable to get upstairs without assistance and since then she had grown more and more inactive. Two or three months before admission the disease began to make rapid strides. Her mind became affected and she grew quite childlike. What little power of locomotion she still retained deserted her and she was quite unable to walk. Persistent pain settled in the back of the neck. She lost control of both bladder and rectum. Her teeth loosened and fell out one after the other without preliminary decay. Her hair, not only on the scalp but from the eyebrows, too, was shed and she rapidly sank into a helpless and apathetic state.

On admission the temperature was 98° F., the pulse was 86, and the respirations were 20. The patient was noted as a little woman with a complexion suggesting the yellow tint

of pernicious anemia. She was singularly dull and listless and the difficulty of communication with her was not lessened by a certain suspiciousness in her attitude towards others. To questions her replies were delayed and were then given in a slow, deliberate manner, with thick articulation. As already mentioned, she was unable to supply details of her past history. She lay still in bed on her back and complained that movement of her legs was painful and of her head very painful. Her arms she used in a slow and lumbering fashion. No teeth remained in her jaws and much hair had fallen out from the scalp but the baldness was more marked in the eyebrows. The tongue was clean but abnormally large. The skin over the whole body was dry, very tough, and yellow, and the slightest touch appeared to give pain, especially on the soles of both feet. The left ankle was red and swollen and the subcutaneous tissue about it pitted on pressure. The hands were cold and spade-shaped and the thyroid appeared atrophied. The pupils reacted to light and accommodation. The calves of the legs were not tender and there was no paralysis though the grip of the hands was weak. Knee-jerks normal; flexor plantar reflex; loss of control of the bladder. The respiratory and circulatory systems presented nothing abnormal. The abdomen was large—35 inches at the umbilicus—but no ascites had formed. The spleen was not palpable but the liver was felt two inches below the costal margin. An examination of the blood showed red corpuscles, 1,700,000 (34 per cent.); white corpuscles, 5000; hæmoglobin, 30 per cent.

The progress of the case was from the first towards a fatal end. The patient's mind wandered considerably and her memory was unretentive of the most recent events. She grew more and more noisy, especially at night, and died on April 2nd, a fortnight after admission. The treatment employed consisted of five grains of dried thyroid extract three times a day and a mixture containing potassium iodide. The former was omitted for a couple of days as it was suspected to be in part responsible for the delirium.

A post-mortem examination was made 12 hours after death. There were old-standing adhesions between the lobes of the lung and between the lungs and diaphragm. The apex of the left lung contained a calcareous deposit and its base showed hypostatic pneumonia. The heart, which weighed 384 grammes, presented some fatty infiltration of the myocardium and hypertrophy of the left ventricle. The anterior cusp of the mitral and all the cusps of the aortic valve were slightly atheromatous, as also was the aorta itself, thoracic and abdominal. The liver slightly fatty and the kidneys with some interstitial nephritis complete the list of organs other than the thyroid and parathyroids which were affected.

Thyroid gland.—A detailed examination was made of the structures in the neck. The whole of the soft tissues anterior to the prevertebral muscles and deep to the sternomastoid were removed *en bloc*, including everything from the tongue to the superior mediastinum. These were carefully dissected and every gland discovered was retained for microscopical section. The thyroid itself in the usual position was remarkably small, pale, and indefinite in outline, merging into the surrounding connective tissue. The isthmus was represented only by a fibrous band spanning the trachea. After dissecting the gland away from its attachments its lobes were seen to have none of the characters (colour, consistency, &c.) of the healthy thyroid and, except at the lower pole on each, none of the usual contour. The whole organ was a thin sheet of fibrous tissue wrapped round the front and sides of the trachea. In close connexion with the right lobe were two parathyroid glands, one lying on the lower part of the lateral surface, the other a short distance inferior to the gland. On the left side were four parathyroids, two large and two minute. Of the former, one lay on the lateral surface of the gland, the other just above the point of entry of the inferior thyroid artery. Close to this last were the two minute parathyroids. All six glands were imbedded in much fat and rested on the thyroid without being depressed into its surface. The four largest were elongated ovoids from 0.5 to 1 centimetre in length, the two smallest being mere pin-heads. All were fairly soft in consistency and of a dirty yellowish-brown colour. On the left side below the thyroid gland were two pale brown bodies, of which the note made at the time of the necropsy was "tough, almost fibrous." The nature of these will be discussed below. In addition to these a large number of glands were examined microscopically but all proved to be lymphatic.

¹ A paper read before the Clinical Society of London on Jan. 11th, 1907.

hæmatemesis. In the other two there had been some, but it had not been a prominent feature. It had only appeared late in the course of the complaint and was not serious in quantity. I looked upon it rather as a consequence of the vomiting. Mælena had not been noted. The onset in all had been very gradual. It was not possible to fix even an approximate date for the beginning. There was a history of long-continued dyspepsia and there were no symptoms sufficiently defined to mark the transition from simple indigestion to a severe degree of pyloric stenosis. In all there was the suspicion of gastric ulcer and at the operation no trace of ulceration or of the cicatrix left by an ulcer could be found either on the serous or the mucous surface.

Whatever may be the pathology of this affection, it is clear that the muscular fibre of the pylorus has disappeared to great extent and been replaced by tough and unyielding fibrous tissue. The serous coat is not involved and there is no evidence of inflammation. There may have been a stage of muscular hypertrophy preceding this, but there was nothing to suggest it in any of my cases. The most probable explanation is that the fibrous degeneration is the outcome of long-continued spasmodic contraction, caused by resistant dyspepsia. In the earlier period if the cause is removed before the degeneration has advanced too far cure may be possible without operation. These are probably the cases in which systematic lavage succeeds. But when that stage is reached in which the pylorus is so rigid that it does not yield to any reasonable degree of force spontaneous recovery is most unlikely. Fortunately gastro-enterostomy, specially that modification described by Finney, can be relied upon to effect a permanent cure with the minimum of risk. I performed it in all of these with the very best result. The pain disappeared. The patients improved in weight and strength, and so long as they took reasonable care they were enabled to lead their ordinary lives and live on ordinary diet.

The question of the time for surgical treatment, therefore, turns upon the stage the fibroid degeneration has reached. Up to a certain point, if the cause that maintains the spasmodic contraction is removed, absorption may take place and the opening regain its elasticity. Beyond that point, whether the cause is removed or not, absorption can do nothing unless it is assisted in some way. The contraction merely becomes tighter. Unhappily the change is so insidious that, as in all my cases, no definite date could be assigned. But it may be taken as fairly certain, if a case is watched for any length of time, that if the dyspepsia returns again and again after apparent cure, and the stomach shows signs of increasing size, especially if at the same time there is evidence that the muscular coat is capable of work, there must be some form of pyloric obstruction and if this does not soon yield to lavage it is better that the patient should have gastro-enterostomy performed than that he should be allowed to continue in a state of constant pain, steadily deteriorating in health and strength.

There is one caution that must be observed. Gastro-enterostomy effects such marvellous results in these cases, that patients, unless they are warned beforehand, are liable to expect too much from it. They are apt to think that they can do what they like and eat what they like, as they did before the operation, forgetting the consequences that followed. It is essential that they should understand what gastro-enterostomy is and what it is intended to do. So far as the difficulty is a mechanical one, to be treated by mechanical means, gastro-enterostomy can be relied upon to effect a cure. It does not treat, or pretend to treat, the condition which preceded the stenosis, and which may continue after the stenosis has been divided. There will not be so much pain, it is true. Such acute attacks of stomachic colic are no longer possible after the contracted sphincter has been divided, and this is one of the great advantages of Finney's method over others. But if the conditions of living which gave rise to the dyspepsia at the first, when the stomach was still perfectly healthy, are allowed to continue, they will give rise to the same results, so far as they can, after gastro-enterostomy has been performed. For want of being cautioned about this patients are sometimes disappointed with the results of gastro-enterostomy. They think that the operation will cure the condition which gave rise to the stenosis as thoroughly as it cures the stenosis itself. I have known several instances in which patients have come back some months after the operation, declaring in spite of their greatly improved appearance and strength that they were as bad as they were before the

operation. It is my invariable rule in such cases to put them to bed, to get the bowels to act thoroughly well, and to restrict them to milk diet for a day or two; and I have never known a case in which the pain did not disappear immediately and recovery follow at once.

Wimpole-street, W.

A CASE OF ABNORMAL DEVELOPMENT OF THE OESOPHAGUS.

By J. E. SPICER, M.A., M.B., B.C. CANTAB.,
RESIDENT ACCOUCHEUR, LONDON HOSPITAL, WHITECHAPEL, E.

DURING the last 18 months three similar cases of congenital malformation of the oesophagus have been admitted to the London Hospital. The anatomical characteristics of two of them, as well as of previously reported cases, have recently been described by Dr. Arthur Keith and myself.¹ The following case has occurred since and has not yet been recorded. I am indebted to Mr. Jonathan Hutchinson, jun., for permission to publish it.

The abnormality is identical with that of the other cases and can be seen in the accompanying diagrams. It is due to maldevelopment of the tracheo-oesophageal septum in the anterior part of the primitive oesophagus. As a result the upper part of the oesophagus is found to end in a dilated cul-de-sac, while the lower opens above into the posterior wall of the trachea immediately above the bifurcation. The history of the case is as follows.

The patient, a full-term female child of 7½ pounds in weight, was admitted to the London Hospital a few hours after birth the subject of imperforate anus. There were no other external abnormalities. The child was operated on but the rectum could not be found. The patient died 22 hours after birth. She was the tenth child and, with the exception of a short umbilical cord which delayed delivery, the birth was natural. The preceding child was described

Fig. 1. Side view.—A, Probe inserted in the larynx passing through the trachea into the oesophagus. U, Upper end of the oesophagus, ending in cul-de-sac. M, Band of muscle fibres and no communicating passage. L, Lower end of the oesophagus.

Fig. 2. Back view.—U, Upper end of the oesophagus, ending in a cul-de-sac. L, Lower end of the oesophagus opening above into the trachea.

Fig. 3. Front view.—A, Opening of the oesophagus into the trachea. S, Stomach.

by the mother as having been a "blue baby with a hole in its heart" which only lived four hours. Previously to this there had been a miscarriage but the rest of the children are alive and well. There is no apparent abnormality in any of them and the parents are perfectly healthy. One maldevelopment-alone is known among the collateral branches

the latter hypothesis as the conclusion most in accord with available evidence, it seems reasonable to suppose that these changes represent an attempt on the part of the parathyroids to supply the deficiency of colloid left by the atrophy of the thyroid itself. The increase of connective tissue, though not excessive, was considerably more marked than I have seen in any other human gland or, with one exception,² in the parathyroid of any mammal or bird. Although five of the six parathyroids were directly continuous with the fibrous capsule of the thyroid, this factor alone will not account for the alterations in the former, because the sixth parathyroid, which lay inferior to the main gland, was quite as affected as its fellows. I look on the increase of fibrous material as pathological, in which case it must be regarded as an early stage of the fibrosis, which had reached so advanced a condition in the thyroid.

In brief, these changes show that the parathyroids have been stimulated to supply in part the want of colloid, but that at the time of death they were being overtaken by the same fibroid degeneration as had destroyed the thyroid.

Harley-street, W.

PYLORIC STENOSIS AND THE CONDITION OF THE PYLORUS DURING LIFE.

BY C. W. MANSELL MOULLIN, M.D. OXON.,
F.R.C.S. ENG.,

SENIOR SURGEON AND LECTURER OF SURGERY AT THE LONDON HOSPITAL.

NON-MALIGNANT stricture of the pylorus may be caused by the contraction of a scar left by an ulcer that has healed or it may arise independently, without any evidence of ulceration or inflammation, from what appears to be fibroid degeneration of the circular muscle that surrounds it. With the former of these I am not concerned at present. The latter, however, I have met with so often of late that unless I have happened to have come across one of those exceptional series of cases which sometimes occur to everyone I cannot help thinking that it is much more common, and therefore more important, than is usually believed.

Before proceeding further, however, it is necessary to define what constitutes a stricture of the pylorus and to form some idea as to what may be the real size and the distensibility of the opening during life. With this object in view, for some time past whenever I have had occasion to open the abdomen for the purpose of operating upon the stomach I have made it a practice to examine the pylorus as thoroughly as I could. The description in the ordinary textbooks is no doubt accurate, so far as it goes, but it is founded on the examination of cases after death and it is reasonable to think that the condition post mortem, no matter how soon the examination is made, is not the same that it is during life. The circumstances are not the same. Not only have the changes that set in post mortem to be taken into consideration but there is the loss of the tonic contraction which is present during life and which does not entirely disappear from involuntary muscles, even when the reflexes are abolished. All cases in which there was obvious disease, such as ulceration or a cicatrix or malignant growth, either at the pylorus or close to it, were placed upon one side and only those recorded in which the pylorus appeared to present no gross change. The patients were under complete anaesthesia, with the voluntary muscles of the abdomen relaxed, and the stomach had been emptied in all of them.

The method adopted was naturally not a very elaborate one. The pylorus in each case was carefully felt from the outside to ascertain if there was any hardness or irregularity, and then while it was fixed with the left hand the index finger of the right was made to invaginate the wall of the stomach some way off and was pressed against, or where it was possible without using undue force pushed into, the pylorus. In this way a rough idea could be formed of the size of the opening (under these conditions) and the degree of resistance which it presented. In those cases in which the stomach was opened the examination was afterwards completed with the finger in the interior.

Under ordinary conditions the site of the pylorus is marked by a narrow transverse groove, slightly paler in colour than the rest. The pylorus itself is firm, almost hard

to the touch, the line of transition being more sharply marked on the intestinal side than on that of the stomach. When grasped between the finger and thumb it often gives the sensation of being nodular and irregular even when there is no disease. This is probably due to irregular muscular contraction, perhaps caused by exposure or by the examination, for it is much less distinct when the finger is passed into the opening. From the interior of the stomach the pylorus feels like a round opening with well-defined edges which just admits the tip of the forefinger. So long as it is normal it yields readily to pressure and there is no difficulty in making the finger, with the wall of the stomach covering it, enter sufficiently far to make sure that the opening is free and soft.

Leaving on one side all cases in which there was some gross lesion, I found that the size of the pylorus varied from that of a channel which could easily admit three fingers with the invaginated wall of the stomach around them to that of a tiny orifice which could scarcely be felt. The former was in a patient who was suffering from general enteroptosis. Probably this extreme dilatation was due to the same cause which produced the enteroptosis. The pylorus was indefinite that it was difficult to find. The sphincter could scarcely be felt, and the stomach and intestine seemed to form one continuous canal without a break. The latter was undoubtedly a case of stenosis, as the muscular coat of the stomach was in a state of hypertrophy, and the stomach during life had been seen and felt to contract through the abdominal wall; but there was no evidence of any scar, and the pylorus, when felt from the outside, did not present any marked degree of irregularity. Between the two I have met with every grade.

The degree of distensibility was no less variable. Normally the muscular tone of the pylorus yields at once to gentle pressure. But in many of these, even in those in which the orifice was not exceptionally small, the pylorus was so hard and rigid that though it might have been torn it would not stretch. When examined from the serous surface there was nothing obviously wrong. The pylorus appeared to be firm, but it was uniform and not particularly enlarged or contracted. On trying, however, to press the finger into it, it resisted in such a fashion as to leave no doubt that, though there was no evidence of a scar or old ulcer, it was the seat of fibrous stricture.

I have recently met with no less than seven cases, all with a strong family resemblance to each other, in which the hardness and rigidity of the opening were such as to merit the title of stricture and in which there was no sign of a scar. The size varied. In one the opening could not be felt at all. On inspection from the interior it was so small that it would scarcely admit a probe. In the others the diameter appeared to range from an eighth to a quarter of an inch but in all alike it was absolutely rigid. When the finger was pressed against it, it was a circular opening in a tensile membrane and it would not yield to any reasonable degree of force. There were no adhesions, nor was there any thickening of the peritoneal covering or any other evidence of inflammation or ulceration. It simply seemed as if the circular muscular fibre had disappeared and had been replaced by tough and unyielding fibrous tissue. In one in which the opening was very small, the walls of the stomach were considerably thickened and the size of the organ appeared to be about the normal. In the others the stomach was distinctly enlarged and the walls did not appear to be materially changed. I do not attach much importance to this, however, as it is very difficult to judge of the thickness of the walls, and it is not unreasonable to think that both the size of the stomach and the apparent thickness of its walls may be considerably influenced by the condition of the patient and of the stomach immediately before the administration of the anaesthetic.

Six of these patients were women; one was a man. All had been sent to me with the diagnosis of suspected gastric ulcer. In each the chief symptom had been epigastric pain, more or less gripping in character, coming on some time after food was taken, not immediately, and continuing for hours with varying severity. It was due, no doubt, to stomachic colic, as in one or two the contraction of the stomach could be seen or felt to coincide with the waves of pain. Emptying the stomach always gave relief, but vomiting was not an early or a prominent symptom unless the patient induced it voluntarily. Superficial tenderness was present in all in the upper epigastric region. Deep tenderness was either absent or very ill defined. In five there had never been

² That of a Malayan bear.

a few outlying patches being present and these not more than one inch from the main mass. The fat around the left kidney showed areas of fat necrosis and this was most marked behind the organ. The pancreas was very large and contained numerous hæmorrhages. The tail of the pancreas appeared normal. Many of the veins in the pancreas were thrombosed. No calculi were found and the pancreatic duct could not be properly dissected out. The tissues around the head of the pancreas, and especially behind it, were infiltrated with blood. The common bile-duct was patent and there were no gall-stones. The stomach contained blood.

CASE 3. *Acute hæmorrhagic pancreatitis*.—Total duration of illness, four days; operation 36 hours before death. The peritoneum contained three ounces of blood-stained fluid. There were small spots of fat necrosis in the mesentery and also in the subperitoneal fat in the anterior abdominal wall. There were large masses of fat necrosis in the fat around the pancreas and in the ascending mesocolon. Small hæmorrhages were present in the fat around the pancreas and at the root of the mesentery. The pancreas was very large and formed a large mass extending across the abdomen. There were hæmorrhages on its surface and on section there was seen to be a considerable amount of hæmorrhage into its substance. There were opaque yellow patches of fat necrosis. The tail of the organ appeared healthy. There was no thrombosis of the veins and the duct of Wirsung was normal and did not contain calculi. There was a considerable amount of fat necrosis around the head of the pancreas and also in the peri-renal fat. There were no gall-stones and the common bile-duct was patent.

CASE 4. *Subacute pancreatitis*.—Duration of illness, between three and four weeks; attacks of abdominal pain for two years; operation two days before death. About two feet of the small intestines were very dark in colour and looked gangrenous. The mesentery of this portion was swollen and engorged with blood. The gangrene of the bowel was due to thrombosis of a large branch of the superior mesenteric vein, produced by an extension of the inflammation around the pancreas. There was no fat necrosis under the peritoneum of the larger sac, but there were large areas in the subperitoneal fat over the pancreas. The head of the pancreas was greatly swollen and somewhat hardened and the fat around was very fibrous. There were some small hæmorrhages in the organ and large areas of fat necrosis were present. There were no large gangrenous portions. The blood in the portal vein was fluid, but there was a thrombus on one side of the lumen which had spread up from below. The gall-bladder had been opened by an operation previously and its walls had contracted down and were thickened. The common bile duct was patent.

CASE 5. *Subacute pancreatitis*.—Duration of illness about three weeks; operation eight days before death. A large amount of fat necrosis had occurred in the edges of the laparotomy wound. There was a little blood-stained fluid in the peritoneum. Numerous areas of fat necrosis were seen all over the peritoneum and some of them were situated very deeply in the subperitoneal fat. They varied in size from that of a pin's head to that of a pea. The spots were most numerous in the great omentum and around the spleen; there were very few in the mesentery of the small intestines. There were large masses in the fat around the kidneys and also small foci in the fat behind the sigmoid flexure and in front of the psoas muscle. There was a large tumour in the region of the pancreas; on cutting through the peritoneum over it a thick fluid exuded which had the appearance and consistency of anchovy sauce. There was a considerable amount of fat necrosis around the pancreas, especially at its tail. At the surgical operation an opening had been made into the fat necrosis below the pancreas and another into the head of the organ. A small portion of the head of the pancreas was gangrenous, while the tail showed the normal lobulation. There were hæmorrhages in the organ around the gangrenous portion. The pancreatic duct was not found and a probe could not be passed into it from the duodenum. There were no calculi. Numerous small points of fat necrosis were found under the parietal pleura on the left side. They were situated on the posterior and lateral aspects of the pleura and in its lower half; none were in front of the anterior axillary line.

CASE 6. *Gangrenous pancreatitis*.—Duration of illness between six and seven weeks; operation three weeks before death. There was suppurative peritonitis, with numerous points of fat necrosis. These were most marked in the great

omentum, varying in size, some being as large as a split pea. The fat necrosis was also seen in the mesentery and in the subperitoneal fat of the abdominal wall. There were no deeply situated areas of necrosis in the subperitoneal fat. All the pancreas was gangrenous except for a small portion at the tail. There was an abscess around the head of the pancreas and in it were large masses of necrosed pancreatic tissue. A considerable amount of fat necrosis had occurred in the fat around the pancreas. In some places there were large masses of it. A probe could not be passed into the pancreatic duct. The gall-bladder was considerably distended and a probe could not be passed from the gall-bladder into the common bile-duct; the latter had been in contact with the abscess and had probably been obstructed by inflammatory changes.

CASE 7. *Fat necrosis after hydrochloric acid poisoning*.—The patient, a man, aged 45 years, was admitted into the General Hospital, Birmingham, in November, 1905, for hydrochloric acid poisoning, under the care of Dr. R. Saundby. On admission the man was very collapsed and died within 24 hours. He was apparently quite well before taking the corrosive poison. At the post-mortem examination there were no signs of corrosion around the lips and no stains or burns on the face. There was no corrosion of the tongue and fauces. Throughout the entire length of the oesophagus there were greyish patches on the mucous membrane. In the stomach the corrosion was extensive and deep. There was charring along the ridges, but there was no perforation. The peritoneum over the stomach was injected. There were acute inflammatory changes in the duodenum and for about the first 12 inches of the jejunum. The pancreas seemed to be normal in size and showed the usual lobulation. There were large areas of fat necrosis on the surface of the pancreas and also in its substance. There was no fat necrosis beyond the region of the pancreas. The pancreatic duct was obstructed by the inflammatory changes. The gall-bladder and common bile-duct were normal. The microscopical examination of the necrotic areas showed that the adipose tissue was replaced by a granular mass, which stained yellow with picric-fuchsin. There were no inflammatory changes around the fat necrosis. The pancreas itself appeared normal.

CASE 8. *Fat necrosis in a case of mitral disease*.—The patient, a female, aged 15 years, was admitted to the General Hospital, Birmingham, in August, 1906, for heart disease and was under the care of Dr. J. W. Russell. There was nothing in the history of the symptoms of the malady which made it appear any different from an ordinary case of mitral disease with failure of compensation. At the post-mortem examination it was noticed that there were general oedema and a slight tinge of jaundice. The heart showed extensive mitral disease, with vegetations on the valve and thickened chordæ tendineæ. The left ventricle was dilated and there was marked fatty degeneration of the cardiac muscle. The pericardium was adherent all over the heart. The peritoneum contained 25 ounces of clear fluid. There were many infarcts in the kidneys and spleen; some of them were old, but many were quite recent. There were many small spots of fat necrosis to be seen on the surface of the pancreas and also a few in the substance of the organ. There were a few points of fat necrosis in the root of the mesentery. The pancreatic duct appeared patent. There were no calculi. The liver showed passive hyperæmia and the gall-bladder was distended. The microscopical examination of the pancreas showed that the areas of fat necrosis were similar to those found in the cases of pancreatitis described in this paper. There were small portions of necrosis of the glandular tissue, but no thrombosis of vessels could be made out.

On two occasions I have attempted to make a chemical analysis of the patches of fat necrosis and have found it very difficult. In Case 5, however, an analysis was made by Mr. J. A. Barnes, B.Sc., A.I.C., and the following is his report: "There is no adipocere present and the spots consist of the calcium salts of a mixture of fatty acids, superlatted. There is no glycerine, leucine, tyrosine, or any other amido-acid present; consequently they are not due to proteid decomposition. The composition of the fatty acids I have been unable to determine on account of the small quantity of material at my disposal."

In only one case was a bacteriological examination of the fat necrotic patches made by culture. The examination was performed with great care and these areas were found to be

of the family; the father's brother has a child with congenital talipes.

On post-mortem examination the following points were noted, besides what has already been described:—1. The right side of the heart was very much larger than the left, and the right auricle was hypertrophied and dilated. 2. No trace of septa in the foramen ovale. 3. The veins from the right lung opened into the left auricle so close to the patent foramen ovale that a large part of the blood probably entered directly into the right auricle. 4. Right and left superior vena cava. 5. No right aortic arch (this was present in the two previous cases). 6. The left ureter showed the presence of a well-marked constriction immediately below the pelvis. 7. Imperforate anus, but the sigmoid well developed. 8. The lungs, intestines, and other organs normal.

It may be interesting to add here, in connexion with this maldevelopment of the oesophagus, that in our earlier cases the children lived respectively six and nine days.

London Hospital, E.

SOME OBSERVATIONS ON FAT NECROSIS.

BY JAMES E. H. SAWYER, M.A., M.D. OXON.,
M.R.O.P. LOND.,

CASUALTY ASSISTANT PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM;
PHYSICIAN FOR OUT-PATIENTS, CHILDREN'S HOSPITAL,
BIRMINGHAM.

DURING two years as pathologist to the General Hospital, Birmingham, I performed eight post-mortem examinations in which fat necrosis had occurred. As probably few medical men can have had the opportunity of observing on so many occasions this interesting condition it seems to me desirable to describe the appearances which were found and to record the results of the microscopical, chemical, and bacteriological examinations which were made in these cases. Three of the cases mentioned in this paper have been published already in various medical journals and they are included in the following list:—

Case.	Age.	Sex.	Disease.	Under the care of—	Where published.	Date of death.
1	43	F.	Acute hæmorrhagic pancreatitis.	Mr. F. Barnes.	Queen's Medical Magazine, vol. ix., p. 72.	August, 1905.
2	41	M.	"	Mr. G. Heaton.	"	May, 1905.
3	48	M.	"	"	British Medical Journal, vol. ii., 1934, p. 1637.	October, 1904.
4	47	M.	Subacute pancreatitis.	Mr. H. G. Barling.	"	February, 1906.
5	54	F.	"	"	"	June, 1906.
6	59 (P)	M.	Gangrenous pancreatitis.	"	British Medical Journal, vol. i., 1905, p. 438.	October, 1905.
7	45	M.	Hydrochloric acid poisoning.	Dr. R. Saundby.	"	November, 1905.
8	15	F.	Mitral disease.	Dr. J. W. Russell.	"	August, 1906.

Fat necrosis is generally considered to be the result of the action of the fat-splitting ferment of the pancreas upon living adipose tissue. The fat in the cells is split up into fatty acids and glycerine by the action of the ferment; the glycerine is absorbed and the fatty acids which remain combine with the calcium salts and so form a soap. The fat-necrotic areas vary in appearance according to their situation. When they lie just under the peritoneum they appear as small round white spots which are from two to five millimetres in diameter. These are the characteristic spots which are seen when a laparotomy is performed by the surgeon. The spots are rarely larger than the size mentioned above, but masses of fat necrosis are often found which consist of many of these areas situated so close together that they are in apposition. The points of necrosis under the peritoneum are never raised above the surface but can just be felt when the finger is passed over them because they are of firmer consistence than the tissues in which they are situated. They are dull white in colour, but sometimes

they are light yellow at the post-mortem examination from being stained with bile. These small spots appear under the peritoneum and sometimes under the parietal pleura and the parietal serous membrane of the pericardium. If one of these spots just under the peritoneum be cut in half it is seen that the whole of the affected portion is of the shape of a split pea, with the flat surface towards the peritoneum. When the spots are situated deeper in the subperitoneal fat they are usually spherical in shape but about the same as to size except when the fat necrosis is in the retro-peritoneal tissue. In the great omentum there were only these small spots and no large masses in my series. The peritoneum over the stomach may also be affected, but it is uncommon to find the necrotic areas over the small intestines, although over the large intestines they are frequently present. In the root of the mesentery and in the subperitoneal fat over the pancreas and the kidneys there are seen large masses of fat necrosis which seem often to have been formed by the direct spreading of the necrotic changes from the pancreas into the tissues around. Sometimes these large masses seem to be the result of small areas of fat necrosis situated close together. In the pancreas there is commonly seen fat necrosis in the interstitial tissue of the organ. The fat necrosis is often present in large masses in the fat behind the kidneys and pancreas and may be found anywhere in the retro-peritoneal fat.

The ages of the patients in the first five of my series is a point worthy of notice. The ages of those suffering from acute hæmorrhagic and subacute pancreatitis ranged from 41 to 54 years, and their ages correspond with what is generally recognised to be the usual time of life in which these diseases of the pancreas occur. Case 6 was stated to be 59 years old, but when seen by me he did not appear to be more than 45 years, so that there may have been a mistake in the record of his age.

It is a very remarkable fact that in the last two cases of my series the fat necrosis was not found associated with any primary disease of the pancreas, but occurred as a result of hydrochloric acid poisoning in one case and in mitral disease in the other.

I do not propose to give a complete account of all the eight cases but only to describe the distribution and the appearance of the fat necrosis and the changes which were found in the pancreas at the post-mortem examinations.

CASE 1. *Acute hæmorrhagic pancreatitis.*—Total duration of the illness, seven days; operation on the second day. The peritoneum was quite dry. There were points of fat necrosis in the subperitoneal fat all over the abdomen. These varied in size from that of a pin's head to that of a pea. Some were stained with bile and had a bright canary-yellow colour. The fat-necrotic areas were situated not only under the peritoneum but also deeply in the subperitoneal fat. These areas were most numerous in the subperitoneal fat lining the anterior abdominal wall and in the great omentum. There were very few in the mesentery of the small intestines and none over the intestines themselves. The peritoneum was swollen and easily stripped off the intestines. In the lesser sac and in connexion with the tail of the pancreas there was a cyst which contained a fluid having the appearance of water. The fluid had a slightly proteolytic action and a markedly amyolytic action. It curdled milk and had a fat-splitting ferment. There were large masses of fat necrosis around the pancreas and also small points in the substance of the organ. Portions of the pancreas looked quite healthy and had their normal lobulation, while other portions were disintegrated and hæmorrhage had occurred in them. No calculi and no obstruction to the pancreatic duct were found. Some of the veins were thrombosed. The common bile-duct was patent. In the parietal pleura on the left side there was a small area of about the size of a shilling in which there were a few points of fat necrosis. It was situated over the vertebral column and just above the attachment of the diaphragm and below the level of the lung.

CASE 2. *Acute hæmorrhagic pancreatitis.*—There was a little blood-stained fluid in the pelvis. Large masses of fat necrosis were present at the root of the mesentery and two small patches in the great omentum. There was no fat necrosis under the parietal peritoneum. Fat-necrotic areas were also found in the transverse mesocolon and in the lesser omentum. There was a considerable amount of fat necrosis in and around the pancreas. The fat necrosis seemed to commence around the pancreas and to radiate from it in the subperitoneal fat, only

nystagmus became much more marked and a decided intention tremor appeared on the right side only, with right-sided patellar and ankle clonus. A very brisk jaw-jerk was obtainable at this time and her speech became altered. For six weeks after this attack she was confined to bed owing to weakness of the right leg. There was a considerable amount of fluid effusion in both the right knee and ankle-joints, which were, however, painless. Incontinence of urine first commenced at this time, intermittently at first but later becoming complete. While in bed during this six weeks the temperature varied up to 102.4° F., and on several occasions there was a difference of four degrees in 12 hours. An interesting feature at this time was the presence of an urticarial rash which extended all over the body, varying in distribution and degree from hour to hour; it lasted off and on for three months and towards the end of February clear bullæ appeared which, broken, left clean, raw, moist surfaces. They developed chiefly on the hands and feet. The only drugs she was using at this time were simple aperients and occasionally small doses of bromides. Whether the urticarial and bullous condition should be attributed to these or to abnormal vaso-motor changes dependent on her disease I do not know. In following April she improved and was allowed out of bed; she gradually gained strength in the right leg until she was able to get from the bed to the chair unassisted. Her speech that month became much worse and very rigid, but could hardly be described as "staccato." At the end of April another seizure occurred, preceded by a fall of temperature. Twitching commenced in the right side of the face and the right arm and leg; speech became unintelligible and wandering and the patient gradually passed into a semi-comatose condition, with clonic spasm of the right arm and leg, which lasted for several days but gradually disappeared with return of consciousness. The pupils varied in size, continually altering from hour to hour, one visit the right being the larger, at the next the left. Intention nystagmus at that period was a constant feature. On the return of consciousness after this attack she was found to be suffering from complete motor aphasia. Sensory hemiparesis was either absent or slight and transient, for within four days from the return of consciousness she could comprehend what was said to her, but it was some days later before she could herself speak, and then for a time she only answered "Yes" to questions put to her, but she would do anything she was told to. Her speech gradually improved and it was then found that there were hyperæsthesia of the right leg and almost complete anaesthesia and analgesia of the left which persisted for many months. Incontinence of urine was continual and in May cystitis appeared but readily yielded to treatment.

In the following September the condition had improved so much that I find a note to the effect that she was out of bed again and having her meals with her friends in the dining-room, to which she had walked with the assistance of both her nurses. Her writing was shaky but clear; she took an intelligent interest in the illustrated papers and played "Patience," of which she was very fond. At the end of October, after another attack, she became bedridden and her symptoms increased in severity. Speech became so bad as to be unintelligible; nystagmus was always present, the spasticity of the legs became worse, and contractures developed. Intention tremor was so marked that she had to be fed and the incontinence of both urine and faeces gradually became complete.

From October, 1903, to March, 1905, numerous attacks of a similar apoplectic nature occurred, after each of which she passed into a comatose state with Cheyne-Stokes respiration for some days. In March, after an attack she became speechless, but noisy, and appeared to be in pain. After several days a large ischio-rectal abscess was discovered and opened. In April she became very lethargic and could not be made to understand anything said to her. She understood, however, to a certain extent, what was going on around her, and would, for instance, help her nurses when washing her. The next month, notwithstanding excellent nursing and a water-bed, a large bed-sore formed on the left hip, followed by an abscess of the buttock, which necessitated very extensive opening and draining with tubes. At that time, too, numerous crepitations were found at the bases of both lungs; and the respiration rate was frequently 30 per minute. The abscess slowly healed and the chest signs disappeared, but from June, 1905, onward, the girl never regained consciousness, hardly ever moving in bed.

During the last 18 months of life it was only with great difficulty and with the occasional help of a nasal tube that her food, which consisted of milk, meat juice, &c., could be given her. She simply lay in bed on her back with her hips and knees flexed and rotated to the right side, her arms flexed and pressed so tightly on her chest as to necessitate her thorax being protected with Gamgee tissue to prevent pressure ulcers. Her legs showed marked emaciation and wasting of muscles, but the rest of her body, with the exception of the hands, remained fairly nourished. In the hands atrophy appeared first in the thenar and hypothenar eminences, and then extended to the interossei; fibrillary contractions were constantly present in the forearm muscles. The tongue, too, showed signs of atrophy. The reflexes slowly disappeared, both superficial and deep, until even the corneal reflex could not be elicited. The pupils towards the end became small and equal, but they always reacted to light. The apoplectic attacks continued and became even more severe in character, leaving the patient collapsed, pulseless at the wrist, and cyanosed; they were almost always preceded by a fall in temperature, so that the nurses were able to predict the occurrence of a fit. These attacks were followed by twitchings and spasms chiefly of the right arm and leg, so severe as to shake the bed. These would continue for hours and were accompanied at intervals by a short, sharp, piercing cry which could only be compared with the meningial cry. They were, to a certain extent, controlled by hypodermic injections of morphine, which had to be given in increasing doses. I am inclined to think that the morphine diminished the number of the attacks. Bromides, even in large doses, had no effect.

Respiration for many months was of the Cheyne-Stokes type, and, at the height of the cycle, when respirations were most active, she frequently uttered this cry, at times so loudly as to provoke complaints from the tenants in the neighbouring flats. The pulse was usually rapid and irregular and at times was imperceptible at the wrist. After the subsidence of an attack, cyanosis, coldness, weak respiration, and feeble cardiac action were so marked that death was often thought to be imminent, and when, after a series of fits lasting for 48 hours, with a gradual rise of temperature to 106°, death did occur on Sept. 5th, 1906, the patient looked no worse than she had done on previous occasions.

The sequence of the classical symptoms of this disease was remarkable, as was also the temperature, which was never what could be considered normal for longer than 24 hours, from February, 1903, to September, 1906. The apoplectic attacks were exactly like true apoplexy, followed by right-sided hemiplegia, and, at first, speech disturbance, but the paralysis was transitory. No post-mortem examination could be obtained.

DYPHTHERITIC MEMBRANE INVOLVING THE PHARYNX, OESOPHAGUS, AND RESPIRATORY PASSAGES.

By F. E. FIELD, M.B., CH.B. EDIN.,

ASSISTANT MEDICAL OFFICER AT THE NORTH-WESTERN HOSPITAL, HAMPSTEAD.

INVASION of the oesophagus by diphtheritic membrane seldom occurs even when there is extensive involvement of the pharynx or respiratory passages. Holt reported on 109 cases of diphtheria and Lennox Browne on 1000 in which there is no mention of membrane in the oesophagus. Codrillman, Malloy, and Pearce have placed on record 12 cases out of 220 examined post mortem in which the oesophagus was part of a general involvement, and Sir Morell Mackenzie mentions cases recorded by other writers and two cases coming under his own observation. The only recent cases of membrane extending to and involving the oesophagus are those recorded by Dr. E. W. Goodall,¹ Dr. E. Cautley,² and Dr. John Fawcett.³

A man, aged 37 years, was admitted to the North-Western Fever Hospital, Hampstead, on the evening of Oct. 9th, 1906, complaining of headache and sore throat. He had had

sterile. Microscopical sections of the areas in other cases never showed any micro-organisms. In some of the cases bacteriological examinations of the fluids from the cysts, of the peritoneum, and of the pancreas were attempted. The bacillus coli communis was invariably found, together with other micro-organisms, but the examination presented so many difficulties that it was not pursued further.

Microscopical examination of the areas of fat necrosis showed that the adipose tissue was simply replaced by a granular material which coloured deeply with various stains. The outline of the cells in which the fat had undergone the necrotic change could easily be made out. There were no inflammatory changes seen around the areas and no micro-organisms were ever found. The microscopical appearance presented in the pancreas varied considerably in different portions of the same gland. In places the organ was quite disorganised and no glandular structure could be made out. Some areas of necrotic parenchymatous tissue were seen, some large and others very small. In other places the pancreas appeared quite normal or only showed cloudy swelling, while in others there were acute inflammatory changes in the interstitial tissue. Numerous small hæmorrhages were constantly present.

From a study of the foregoing cases it appears that in some the fat necrosis was more abundant near and around the pancreas than anywhere else. This suggests that the fat necrosis commenced in the immediate neighbourhood of the gland and was the result of the leakage of the pancreatic secretion into the tissues around. That this occurred is supported by the fact that large masses of fat necrosis were often found behind the pancreas and around the kidneys. As a result of disease of the pancreas the fat-splitting ferment may escape directly into the neighbouring tissues, as is suggested above. It may, however, be carried there by the lymphatics. Probably both means of distributing the ferment occur. In other cases the distribution of the points of necrosis all over the peritoneum indicates that the pancreatic juice has escaped into the general peritoneal cavity and that it has acted upon the subperitoneal fat, possibly by gaining access to it through the stomata. Microscopical examination, however, has not demonstrated that stomata are to be found over fat necrotic areas. Fat necrosis was found in Case 5 in the edges of the laparotomy wound and this was without doubt caused by the ferment in the general peritoneal cavity, escaping from it rather than that the ferment was carried to the wound by the lymphatics. It is easy to understand how the fat-splitting ferment may escape into the tissues, around the pancreas and even into the peritoneal cavity when there is destruction of the gland, as in acute hæmorrhagic, subacute, and gangrenous pancreatitis. So also may it escape in disorganisation of the pancreas by the action of a corrosive poison. But it is difficult to explain this escape in a case of heart disease. Even in Case 7, in which the necrosis followed hydrochloric acid poisoning, there seemed to be very little, if any, damage of the pancreas. It does not seem possible for the escape of the fat-splitting ferment to be produced by simple catarrhal obstruction of the pancreatic duct, for otherwise fat necrosis would occur very much more frequently than is the case. In catarrhal jaundice there would be reason to expect an obstruction in the pancreatic duct as well as in the common bile duct, but it is obvious that if this occur the fat-splitting ferment cannot be commonly absorbed by the lymphatics, as the bile is in obstruction of the common bile duct, for otherwise fat necrosis would be a much more usual event in practice. To produce fat necrosis it seems therefore that something more is required than merely obstruction in the pancreatic duct; it seems that some destruction of the pancreatic tissue is also necessary.

In Case 7 the fat necrosis was probably due to the damage or injury of the pancreas by the corrosive poison, although any change in the organ was not very obvious, and not to the obstruction in the pancreatic duct, although such obstruction may have contributed to the escape of the fat-splitting ferment. In Case 8 there may have been some catarrhal obstruction of the pancreatic duct as there was slight jaundice. Small areas of necrosis of the parenchymatous tissue of the pancreas, however, could be demonstrated. It is hardly possible that the fat necrosis which was found in the pancreas was merely a post-mortem change. The explanation of the presence of fat necrosis in this case would seem to be that multiple emboli had occurred and produced necrosis of the parenchymatous tissue of the pancreas with a subsequent escape of the fat-splitting ferment.

Although some destruction of the pancreatic tissue seems to be a necessary factor in the production of fat necrosis, yet in cases of extensive disease of the pancreas fat necrosis does not always occur, as was shown by a case on which I performed a post-mortem examination for Mr. L. P. Gamgee in October, 1904. The patient was aged 32 years, and there was an abscess in the head of the pancreas containing three ounces of thick pus. He had received a violent blow in the centre of the abdomen from the shaft of a cart, and there is no doubt that the pancreas was injured at the time. A large portion of the pancreas was gangrenous and the case appeared a typical one for the occurrence of fat necrosis, but none was found. The patient died 11 days after the accident.¹

Eppinger² has suggested that the areas of fat necrosis are infarcts arising by the displacement of small portions of pancreatic tissue along the path of the lymphatics and that this tissue contains "activated" pancreatic ferment. There are three points in my cases which seem to oppose this view—namely, (1) the areas of fat necrosis are sometimes seen just under the peritoneum and nowhere else, except in the immediate neighbourhood of the pancreas, indicating that the ferment had escaped into the general peritoneal cavity; (2) the fat necrosis was observed in the edges of a laparotomy wound; and (3) the radiating appearance of the fat necrosis in one of the cases seems to point to direct extension from the pancreas.

My thanks are due to Dr. Saundby, Dr. Russell, Mr. Barling, Mr. Heaton, Mr. Gamgee, and Mr. Barnes for their kind permission to make use of their cases in this paper.

Birmingham.

NOTES ON A CASE OF DISSEMINATED SCLEROSIS.

BY Z. MENNELL, M.B. LOND., M.R.C.S. ENG.,
L.R.C.P. LOND.

DISSEMINATED sclerosis is frequently seen in its early stages at the hospitals and in its later stages in the infirmaries but is comparatively rarely seen in private practice throughout its whole course by the same observer; hence I venture to publish the following brief notes of a case which I had under my care from a very early stage up to the patient's death. In the course of her illness she showed a great many of the symptoms accredited to this disease and some which I have not been able to find described.

Early in November, 1902, I was called one evening to see a girl in a "nervous fit." The patient, aged 20 years, had a bad family history, being the illegitimate daughter of a man who had undoubtedly had syphilis and who died, when the girl was 16 years old, from general paralysis of the insane, and of a woman who was a dipsomaniac. Her previous history showed nothing of importance, except that her education had been somewhat neglected. Her father left her well provided for. She herself was a girl of medium height, rather inclined to be fat, and fairly intelligent; she had been suffering from attacks of giddiness, which had culminated in the fit for which I was called. When I arrived the fit was just over. The girl was lying on a bed complaining of having fallen and bruised her leg; she was rather excited and showed no signs of any disease other than slight lateral nystagmus and increased reflexes of the legs which led me to make a provisional diagnosis of disseminated sclerosis. A few days later, after using a mydriatic, I found that both optic discs were distinctly pale on the temporal side. There was also marked dorsiflexion of the great toes in response to plantar stimulation. From this time until her death in September, 1906, I saw her constantly, the symptoms being progressive.

The patient was quite intolerant of iodides, so late in December, 1902, mercurial inunction was tried for two months. In February, 1903, without any warning she was suddenly sick and had an apoplectic seizure. She had conjugate deviation of the head and eyes to the right, her pupils were dilated, her face was flushed, and she had stertorous breathing. In this condition she was carried to bed where she remained unconscious for some hours, not responding to any external stimuli. After this attack the

doubt, by a delay in applying to a superior authority at once, be it a senior or better-informed man or a clinical research laboratory. Never, however, must what another has done be given as direct evidence in a court of law. Thus, in 1902, Sir Thomas Stevenson was stopped at the Central Criminal Court, when he wished to testify as to the results of some toxicological examinations which his laboratory assistant had made. Sir William Jenner's advice is pertinent in this connexion: "Never believe what a patient says another doctor said." It is a presumption of the law that all "qualified medical practitioners" are competent professional advisers; this to some extent explains the attitude of the public to differences of medical men, medical men's dilemmas, and dubious diagnoses. Medical witnesses should be continually mindful of the fact that counsel will probe what they have omitted to do. An authority, so-called expert, would be less likely to quail before such questionings, but there are some matters in which the only expert, or at least the most expert, is the prisoner standing in the dock. Such a person, with malice aforethought, may have confused, fictitiously and factitiously, the differential signs usually indicative of murder, suicide, or accidental death. Our medical forefathers, innocent alike of morbid anatomy and of analytical chemistry, were safe only because counsel were, if possible, still more ignorant. Sir Robert Christison in 1857 was made to withdraw an emphatic statement as to the tastelessness of white arsenic when a junior counsel confronted him with a new edition of Orfila. In studying the old records which bear upon legal medicine many annoying omissions are met with. The depositions in the State trials concerning the birth of the son of King James II.'s wife are not full enough to tell us if he was born alive or born dead; in other words, whether the Old Pretender was supposititious or not (1688). The records of the sudden death of Sir Edmund Bury Godfrey still leave it a subject for discussion whether he was murdered or he slew himself (1678).² The recurrence of the inquest jury's verdict after a view of the body, "*Morbus caducus*," is far too frequent to be definite. Such vagueness, at a later date, led Dr. Farr to advise coroners to be more precise (1842, Fourth Report).

Certain facts of common knowledge are supposed to be admitted in court as "being in the ordinary course of nature" or as being within the judge's memory. An obsolescent limitation to medical evidence may arise, however, from the incredulity of the Bench, as where in 1857 Lord Chief Justice Cockburn discredited the testimony offered from microscopic signs; at times a similar incredulity as to newly discovered facts has been exhibited when specialists have given evidence before Royal commissions—an example being the alleged rate at which railway trains would run.

Occasionally evidence is demanded which appears to be beyond what current medical teaching demands; thus the London County Council (Education) Public Health Authority wishes to insist on a certificate that the throat of a child who has been exposed to infection is bacteriologically free from diphtheria before the child returns to school. It is a nice point for discussion how far a general medical practitioner can be compelled to give reasons on a certificate for his opinion that a child is "free from infection."

Another relative limitation arises when some restriction is imposed upon the medical witness while, wittingly or unwittingly, he is qualifying to give his evidence. Thus when a full physical examination of a person cannot be obtained, or when consent to conduct a post-mortem examination is withheld, there are several matters which otherwise might be made patent but which will in the circumstances remain obscure. To-day this form of limitation is made less noteworthy as a full physical examination is gradually becoming customary: this applies both to clinical and to post-mortem work. One is reminded in this connexion of Sir William Jenner's aphorism: "More mistakes are made, many more, by not looking than by not knowing." The advice tendered to Roderick Random at Surgeons' Hall, "Give me ocular demonstration," is to a similar effect. I am told by aged practitioners that the modern method of fully exposing the affected part of a patient was not clinical etiquette in their young days, just as it was hardly the thing to remove your coat, even in obstetrical practice, before you set to serious work. As to the need of post-mortem examinations, on several occasions has this society assented to a condemnation of the practice of giving medical certificates as to the cause of death, or of propounding medical testimony in cases

where a necropsy should have been performed but was not permitted.

I should classify occasions where a post-mortem examination is essential under the following heads. 1. A post-mortem examination is necessary to test the truth of an alleged death by drowning. Otherwise, in the absence of eye witnesses of the fatality, the open verdict, "*Found dead in the water*," is the only possible conclusion. 2. A post-mortem examination should be made before an infant is said to have been "*overlain*," otherwise the open verdict, "*Found dead in bed with the parents*," is preferable. Both in alleged drowning cases and in alleged deaths from "*overlying*" when necropsies are allowed by the coroner not uncommonly some unsuspected malady is revealed, more especially relative to the cardio-respiratory system; thus heart disease in the former cases may have led to syncope and "*cramp*," and broncho-pneumonia in the latter cases may have made the infant's vital spark very dim and easily extinguishable by the lack of fresh air under the bed clothing. Foul play may be discovered—it will be recalled that King Ben-Hadad was suffocated by Hazael with a wet coverlet when he was ill in bed. 3. In cases of alleged stillbirth a necropsy will show if the child had probably lived after birth, although in the absence of an eye-witness the mere medical evidence will count for little. Years ago "*that hydrostatic humbug*" was derided. 4. A most important series of cases where necropsy should be demanded is where civil or criminal proceedings may arise out of the death—whether such proceedings may be taken against the advising medical man or some other person. Thus, where a charge of negligent treatment is preferred or where a criminal homicide may have been the cause of death a coroner will nowadays always order the body to be opened. Lastly, certain alternative conditions cannot be differentiated without the aid of some special chemical reagent or instrument—thus, a gastritis may otherwise be confused with incipient decomposition of the gastric mucosa, especially in the case of infants. All such laboratory work must have been personally superintended by the witness, otherwise the man who actually did the experiment must give the evidence.

The second variety of limitation owing to the lack of sufficient medical knowledge is not relative to the medical witness personally, but is a general inability to make a positive declaration owing to the uncertainty, insufficiency, or inconclusiveness of the facts available. Even real authorities in this variety of limitation may have to confess that they do not know certain facts, or will when pressed offer a very guarded opinion. Thus in questions of prognosis the commendable attitude may be illustrated by an aphorism of Dr. Samuel Gee: "There is only one thing certain in giving a prognosis in phthisis—namely, that you will certainly be wrong." Further, in questions of malingering the very elect may be nonplussed, as is witnessed in Dr. Weir Mitchell's "*The Autobiography of a Quack*." The physicians of the early eighteenth century would have difficulty in discovering the fraud of Clarissa Harlowe's lover's hæmoptysis of fowl's blood. A few definite instances of such limitations due to unavoidable ignorance are as follows: 1. The exact age of a living man, woman, child, or infant cannot be determined apart from a birth certificate. The age of a skeleton, after complete ossification, is guess-work. The sex of a very old or a very young person's skeleton cannot be determined. 2. In the absence of foetal heart sounds pregnancy cannot be affirmed until quickening has been felt by an observer or the foetal parts are palpable. Affiliation to a putative parent on account of an alleged personal resemblance is insufficient. Chastity cannot be impugned from an inspection of the hymen. 3. The presence of gonorrhoea cannot be established by microscopical evidence. 4. A small mammalian blood-stain cannot be sworn to be "*human*" unless its origin was witnessed. It has been suggested the analyst might aid by declaring the ratio of potassium to sodium salts. 5. Death seldom can be certified until putrefaction has set in. In the case of a sudden death, it cannot be stated whether an unwitnessed suicide was inflicted immediately before or immediately after the death. 6. That a man was drunk when he died can seldom be substantiated by a post-mortem examination of his body. 7. That an alleged "*uncontrollable impulse*" was not merely an uncontrolled impulse, Baron Bramwell used to say: "By an uncontrollable impulse, I mean, an impulse uncontrollable in the absence of a policeman."

The last variety of limitation is that imposed by the rules

² Law Quarterly Review, October, 1907.

no previous illnesses. His surroundings both at home and at work were good—the patient occupying a good social position. A history of alcoholic excess, extending over many years, was obtained. His illness began on Oct. 5th, when he complained of headache and sore throat. His constitutional symptoms on that day were so slight that he did not think his condition warranted his having medical advice. On the following day (the 6th) the patient suffered from chilliness, and this in addition to his other symptoms necessitated his remaining indoors. On the 7th he had attacks of nausea and vomiting. His throat caused him more discomfort and constitutional disturbance was a marked feature. Two days later (the 9th) he received medical attention and was sent to hospital. His state on admission was as follows. The face and lips were cyanosed and the tongue was coated. The soft palate, uvula, tonsils, and the pillars of the fauces were much swollen. Membrane, thin, friable and fibrinous, covered the uvula, both tonsils, and the posterior pharyngeal wall. The cervical lymph glands were slightly enlarged. The temperature was 101.6°F . and the pulse was 88, small, and irregular. The urine contained a large quantity of albumin. Breathing was difficult and hurried and dulness extended over the lower lobes of both lungs. Swallowing was difficult and painful. During the night of the 9th the patient became restless and delirious. On the following morning he had an attack of vomiting and a tube of membrane was brought up. Breathing, however, was not relieved, but swallowing became less difficult. Later, he became more restless and delirious. His pulse varied from 100 to 120 and became more irregular. Respiration increased in frequency and cyanosis was a marked feature. As regards treatment, the patient was given 2000 units of antitoxin a few hours before admission. And on admission another 10,000 units were injected, followed by 12,000 units 12 hours later. Treatment was altogether useless and he died 24 hours after entering the hospital.

Necropsy.—The body was found to be that of a well-developed and muscular man. Rigor mortis was present in both upper and lower extremities, with well-marked general lividity. The tonsils were swollen and ulcerated, and flakes of membrane were present on both. The laryngo-pharynx was covered with dense, tough, yellowish membrane, and traces of membrane were present along the œsophagus to about three centimetres from the cardiac orifice of the stomach. These scattered areas of membrane on the œsophagus were the remains of the cast passed immediately before death, the cast measuring some three to four inches in length. The epithelium of the œsophagus was necrosed and there was congestion of the mucous surface. Membrane covered the valleculæ, the lingual surface of the epiglottis, and the aryteno-epiglottidean folds. The posterior surface of the epiglottis was injected; but the probability is that the membrane there had loosened after antitoxin treatment. The false and true cords and the laryngeal sinus escaped. Beginning immediately below the true cords the membrane continued downwards, completely lined the trachea and larger bronchi, and extended even to some of the minute bronchi. The left lung weighed $3\frac{1}{2}$ ounces and the right $2\frac{1}{2}$ ounces. Areas of broncho-pneumonia of hæmorrhagic variety were scattered throughout both lobes of the left and the lower lobe of the right lung. Areas of collapse were present in both lungs. The left pleura showed traces of past inflammation. The heart weighed 16 ounces. The right chambers and the tricuspid orifice were markedly dilated. There was slight dilation of the mitral orifice, the left ventricle, and the left auricle. There was considerable loss of tone of the organ, and fatty change was marked. Patches of atheroma were present on the ascending aorta. The liver weighed 58 ounces. There were fine cirrhosis and areas of fatty change throughout the substance of the organ. As regards the spleen the Malpighian corpuscles were greatly enlarged and the pulp was somewhat diffident. Both the kidneys were enlarged. The capsules stripped readily. The glomeruli were enlarged and the venules were dilated. The superficial and interpyramidal cortices were swollen and showed marked fatty change.

Bacteriology.—On admission a swab was taken from the throat and a culture was made on blood serum. The colonies consisted of various varieties of streptococci and staphylococci, but the Klebs-Löffler bacillus was not isolated. A second culture was made from the membrane post mortem and almost a pure growth of the specific bacillus found.

Remarks.—The importance of an early diagnosis in cases of diphtheria cannot be too strongly emphasised. In this

case the patient suffered from the disease five days before his case was diagnosed and before he received suitable treatment. 12 hours after antitoxin was given the œsophageal membrane loosened, but toxæmia was too far advanced to allow of efficacious treatment. It is probable that over-indulgence in alcohol contributed largely in lowering the vitality of the tissues and this diminished resistance, together with the delay in treatment, allowed the specific organisms full scope to work their malign influence. Another feature in this case was that even when the membrane had been observed and diphtheria diagnosed the first culture made from the throat gave a negative result. Similar results have often occurred in my experience and when one considers the importance of an early diagnosis it would seem best that in all cases in which diphtheria is suspected at least two separate swabs should be taken on first examination of the throat.

I am greatly indebted to Mr. F. N. Hume for permitting me to record the case.

Note by Mr. HUME.—A remarkable feature in this case was the persistence of phonation. In adults where the air passages are wide the loss of voice is important as an indication of the presence of membrane in the larynx and possibly below it. The absence of laryngeal obstruction without loss of voice may be misleading, but increasingly ineffective inspiration without laryngeal symptoms should be recognised as a sign of bronchial obstruction, its significance rendered more grave by the fact that in such cases of pulmonary suffocation, now of very rare occurrence, tracheotomy is useless. The vocal condition in this case is explained by the freedom, found post mortem, of the vocal cords from membrane.

North-Western Hospital.

SOME LIMITATIONS OF MEDICAL EVIDENCE.¹

BY STANLEY B. ATKINSON, M.A. CANTAB., M.B.,
B.Sc. LOND., J.P.,

BARRISTER-AT-LAW; HONORARY SECRETARY OF THE MEDICO-LEGAL SOCIETY.

THE science, the art, and the correct estimation of the value of medical evidence is the province of forensic medicine. It is not impertinent, therefore, to inquire as to what limitations can be and are placed upon the medical man who desires to bear testimony in a court of law as to facts within his personal knowledge. Evidence is the means whereby an alleged matter of fact, the truth of which is being submitted to forensic investigation, is established or disproved. Testimony is such evidence as is given by word of mouth. Usually medical men are skilled common witnesses of fact; often they are asked for opinions inferred from such facts as they narrate. In offering such consequential testimony they must recollect that they are posing as experts; they would be wise in many cases in just stating what they actually found, without drawing a possible conclusion. In such a case John Hunter in 1781 twice told the judge: "I can give nothing definite."

Limitations of medical evidence may arise in two directions—limitations of medical knowledge and limitations imposed by the policy of the law. The former restrictions become fewer with the advance of time, research, and medical education—for men's views narrow with the progress of the sciences. Limitations imposed by rules of law are enlarged less easily; indeed, modern statutes are notorious for the strictness of their definitions—a strictness which often makes it difficult to bring home wrongdoing to a culprit's door. All definition implies limitation. In this connexion it has been said that in forensic medicine the law leads and medicine follows, whilst in State medicine medicine leads and the law follows.

Limitations of medical knowledge may be relative to the medical witness concerned (self-imposed or enforced), or they may be absolute. Thus the diligence, skill, and knowledge of medical men vary from age to age and from person to person. So variable is this range that a man is expected to treat a patient only to the best of his ability and not in the best manner possible by an authority on such matters. Recognising personal limitations, it is wise for all professionals to be on their guard and to risk no disgrace, when in

A paper read before the Medico-Legal Society on Dec. 11th, 1906.

from time to time, as it tends to get weaker, but the instrument is so arranged that this can be done by tightening a buckle of the strap from which the tendon springs. The accompanying reproduction of a photograph shows the arrangement of the artificial tendo Achillis.

MALGAIGNE'S HOOKS FOR FRACTURE OF THE PATELLA.

By J. E. S. BARNETT, F.R.C.S. ENG.

I RECENTLY at the Kingston Victoria Hospital had a case of broken knee-cap in a short, stout, muscular man who refused wiring. Seeking something which offered better results than bandaging with extension I decided to use the hooks, though most text-books "damn" them "with faint praise." I had not used or seen them used before. The index finger had plenty of room between the two fragments when pressed down through the swollen tissues. On the third day after the fracture, with the patient under chloroform and after aspiration of the joint, the fragments were very vigorously rubbed together. Four snicks with a scalpel down to the bone made way for the hooks, which were fixed well home and screwed up as tightly as possible, so as to lock the two halves firmly together. Now, after six weeks, the result is bony union.

The advantages of the hooks are their facility of a plication by the general practitioner. They lie in front of the joint cavity, with a minimum risk of joint sepsis, and there is a good chance of bony union without the continuous presence of a foreign body such as wire between skin and bone. I had difficulty in removing them owing to the thread of screws and bolts becoming filled by a sort of rust produced by iodoform powder and gauze. This could have been prevented by the occasional use of carbolic oil.

Kingston Hill.

NOTE ON A CASE OF DORSAL DISPLACEMENT OF THE ARM IN VERTEX PRESENTATION.

By ARTHUR G. WELLS, M.B., B.S. LOND., M.R.C.S. ENG., L.R.C.P. LOND.

THIS was a case, in private, of recent occurrence of a woman, aged 33 years, who was pregnant with her second child. The patient was very large and caused me, previously to examination of the abdomen, to suspect twins. Abdominal examination, however, revealed the presence of one child only occupying the second position, but an apparently excessive amount of liquor amni. The pelvis was found to be very capacious and the os uteri was almost fully dilated. The pains were short and weak. I proceeded to rupture the membranes immediately and a great gush of liquor amni occurred, much in excess of the average amount. The labour then progressed rapidly and within 20 minutes the head passed the vulva. Now came the interesting part of the labour. The head, instead of being completely born as far as the neck, stopped short after the forehead, nose, and lips had passed over the perineum, leaving the chin from just below the lower lip still within the vulva. In front the head was born to a little below the occiput and at the sides the ears were just born. Two or three more pains followed but no further advance of the head took place; but it was noticed that with each pain there was a bulging on the right side of the vulva, suggesting that something was, so to speak, hooked in the side and prevented the oncoming of the head. I then proceeded to pass the fingers between the vulva and the child's face into the vagina in the position of the bulging spot, and immediately came upon the elbow, which was caught in the side of the vulva, and on tracing the forearm forwards the hand and wrist were found to be lying behind the child's neck. I then brought the forearm down by the side of the face, converting the condition into one of head and arm, and the rest of the child was easily born with the next pain, with a very slight tear of the perineum. Whether this was due to the excessive amount of liquor amni present, and the child pressed in this condition right through the bony canal or not, I am not prepared to say, but such was the state of affairs at, and just within, the vulva.

Cognisant as I am of the very exceptional occurrence of this condition—in fact, some authorities deny even the possible existence of it—and also quite awake to the

difficulties of making a certain diagnosis, I have labelled this a case of dorsal displacement of the arm in vertex presentation, and with the above facts before one the case seems to me open to no other interpretation.

THE ELIOT COTTAGE HOSPITAL, HAYWARDS HEATH.

A CASE OF TRAUMATIC POPLITEAL ANEURYSM.

(Under the care of Mr. C. R. KEYSER.)

A MAN, aged 51 years, a gamekeeper, was sent into the hospital on Sept. 17th, 1906, by Mr. R. F. H. Newton of Balcombe, who asked Mr. Keyser to see him with a view to surgical treatment. The history was as follows. On March 1st, 1905, he was shot by a shot-gun in the right popliteal space at about five yards range. A large wound resulted which bled profusely. Many shot were removed and the wound eventually healed by second intention in about three months' time. For the last year the patient had been unable to work owing to a large painful swelling in the popliteal space that produced pain and swelling in the foot and leg which were much aggravated by standing. For the last nine weeks the swelling behind the knee had much increased in size and the pain and swelling of the foot and leg had also become greater. For one month a small ulcer had been noticed on the under surface of the big toe, opposite the base of the last joint, which exuded a foul-smelling discharge. When Mr. Keyser first saw the patient on Sept. 17th, 1906, he was a healthy looking man. There were a great deal of wasting of the muscles of the right thigh and œdema of the leg as high up as the knee. The skin of the leg was much thickened and dark reddish-brown in colour. The skin of the toes, especially the big toe, was greatly thickened and almost papillomatous in appearance but only on the dorsal surface. The temperature of the two lower limbs was equal and there was no tenderness except over the middle of the right popliteal space. The right foot was sweating freely and on the plantar surface of the big toe was a small, very recently healed, ulcer. Two small shot were felt just under the skin, one just above the head of the fibula and one on the outer side of the knee joint just above the patella. In the popliteal space there was a great deal of scarring; in the middle line particularly there was a large firm mass of scar tissue adherent to the skin and to the tendons, especially the biceps. Occupying the centre of the space and also the outer side was a large rounded swelling of about the size of a small Tangerine orange; expansile pulsation was present, which was readily controlled by pressure on the femoral artery. The pulse on the inner side of the ankle could be felt with difficulty but that on the anterior aspect of the joint could not be distinguished. There was, practically speaking, complete loss of sensation all over the dorsal surface of the foot, the toes, and the outer side of the leg, with the exception of the little toe. On the sole of the foot sensation was present but was much less than normal. Movement at the knee-joint was very good but the toes and ankle-joint were practically immoveable, both actively and passively.

As the symptoms seemed to be due to pressure of the aneurysm on the veins and nerves, Mr. Keyser thought that operation would only be of service if directed to the aneurysm itself in the popliteal space. Although the prospect of removal of the whole sac of the aneurysm did not appear to be very promising owing to the amount of cicatricial tissue present and the probable adherence of the vein and nerves to the sac and the tissues around, yet it seemed that it ought to be attempted owing to the rapid increase in size of the aneurysm and the pain and suffering which

and policy of the law; it arises on account of the essential strictness of the presumptions and of common law or statutory definitions which become more rigid with modern legislation. Thus crimes must be defined in exact terms and the medical facts must, to be of any avail, be capable of being pigeon-holed—counsel will endeavour, as they did in the bad old days of special pleading, to fit the facts into a loophole if possible. Loose popular phraseology has led to occasional surprise in this connexion; thus, in a moment of righteous anger we may say of drunkenness, "It's a crime," but as a matter of fact the law books do not recognise it as such, although it may incidentally or consequentially lead to the commission of crime.

The English law places no limitation or restriction upon testimony on the ground that the evidence was gained under the privileged circumstance of a medical adviser treating a patient—that is to say, there is no such privilege recognised *de jure*, but few judges would strive to extract such testimony from an unwilling witness. On the other hand, no limitation arises from fear of defaming another in the witness-box, for all statements made after being "sworn" are privileged. There are, however, a few limitations imposed on medical witnesses by rules of law. Medical men, as such, cannot give evidence on certain points. Thus the court will not be influenced by medical evidence which shows: 1. That a woman or a man is past the age for procreation and in the case of the former for bearing children. To the medical mind it appears *prima facie* that a medical certificate could summarily settle the point. But the legal mind considers the admission of such a practice as well indecent as capable of too wide an extension. Thus in 1787 Lord Kenyon (M.R.), when asked to declare that a septuagenarian couple was past the age for procreation, declared "if this can be done in one case it may in another, and it is a very dangerous experiment and introductive of the greatest inconvenience to give a latitude to such sort of conjecture." He was evidently suggesting that the principle might be applied to much younger women, sterilised perhaps by surgical means, and *pro tanto* to men should mere medical evidence be admissible. In these matters the law will not often inquire beyond *habilitas ad matrimonium*, the test of which in practice is mutual ability to consummate marriage. 2. That a child born nine months after lawful wedlock is illegitimate. 3. That, in the absence of eye-witnesses, a newly born dead child was born alive. 4. That, in a common disaster, a certain person must have died last. 5. That children under seven years of age are capable of giving "consent" or of committing an indictable offence. The ground upon which these legal presumptions are based is to prevent vain, futile, and often irrelevant discussions upon subjects which are often beyond the knowledge of mankind. In some continental systems of law, where codification is the rule, there are many more dogmatic presumptions; it is claimed that such presumptions prevent perjury and waste of the court's time.

In conclusion, I think it is wise occasionally to take stock of our present ignorance as well as of our present knowledge and it is with that object that this brief paper has been compiled.

Adelphi terrace, W.G.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES OF THREE CASES OF RUPTURE OF THE TENDO ACHILLIS: TWO COMPOUND AND ONE SIMPLE.

By W. H. BROWN, M.Sc. LEEDS, F.R.C.S. IREL.,
CONSULTING SURGEON TO THE GENERAL INFIRMARY AT LEEDS.

THE following three cases have come under my care in private practice during the last year. Before this, in five-and-twenty years, I have never seen a case, either in hospital or outside. My object in putting the cases on record is to draw attention to the appliance I devised for the after-treatment, which succeeded in each instance in preventing anything like stretching of the healed tendon.

CASE 1.—A medical man, a little over 40 years of age, was playing tennis when he made a great effort to take a ball very wide of him; he felt something give in his

heel, fell as though shot, and had to be carried off the field. When I saw him there was rupture of the tendo Achillis. The gap between the two ends was wide enough to admit two fingers being depressed between them. I put the limb up in the position of talipes equinus, and maintained it in that position by means of an anterior telegraph wire splint. At the end of a fortnight I put the limb up in plaster, and in a month from the date of the accident the patient was able to wear the apparatus described hereafter. This he wore daily for three months. Now the limb is perfectly sound.

CASE 2.—A youth, aged 20 years, wished to wash his feet and attempted to accomplish this by standing with one foot in the lavatory basin. The basin gave way and its broken edge cut sheer through all tissues down to the bone at a point about three inches above the ankle joint. Under an anæsthetic all was made as clean as possible and the out edge of the tendon stitched with silk. In this case I made use of what is described as a "pilot" stitch—that is, a stout silk suture passed through both ends of the tendon and one and a half inches from the out edge, this being drawn tight, leaving the out edges quite slack and enabling the line of suture to be put in without any tension—a distinct advantage—and a method I have adopted in nerve sutures for some years with gratifying results. The skin wound was closed with silk-worm gut and the limb was put up as in Case 1, leaving, however, the bandage in such a way that the antiseptic dressing could be changed without disturbing the splint. The patient made a rapid and uneventful recovery. The youth is now able to indulge in the usual athletic pursuits—i.e., cricket, tennis, golf, &c.

CASE 3.—A man, aged 50 years, seen with Dr. Arthur Hutton of Leeds, attempted to wash his feet in the same fashion as the patient in Case 2, and again the basin gave way, cutting through, obliquely, all tissues down to the bone. Under an anæsthetic the needful cleansing was carried out and a similar line of treatment was adopted as in Case 2. Again, there is nothing of interest to record, the wound healing rapidly, the patient walking about with the assistance of the appliance which I will now describe.

To prevent the obvious danger of stretching the tendon by too early strain I had a boot made, attached to which was an

artificial tendo Achillis made of powerful elastic and leather. This was fixed to the limb by two circular broad bands of leather, about six inches deep, one embracing the calf, the other the same depth surrounding the thigh just above the knee. They girths were joined together by stout webbing. They give a satisfactory purchase and the patient cannot overstretch his tendon. Of course, the elastic needs adjusting

case now under observation. I believe acute rheumatism had nothing to do with the case, for although the mother said that the boy had growing pains he had none of the tenderness associated with this affection. I likewise believe that the presystolic mitral murmur was not a factor in the peri-arthritis, or one often finds this sign in children without any apparent cause. The hardness of the glands is certainly suggestive of syphilis but the boy had no other manifestations of this disease. The blue ointment employed in the treatment was prescribed with no other object in view than the reduction of the peri-arthritis thickening. Those of us who saw the boy were struck with the benefit which followed the taking of the perchloride of iron and glycerine mixture. After considering the whole subject it seems to me that a careful examination of the blood offers the likeliest source of light on the pathology of the affection and when I have another case I shall have repeated differential counts made.

PATHOLOGICAL SOCIETY OF LONDON.

Observations on MacConkey's Bile Salt Neutral Red Medium.
—Typhoid Fever Diagnosed by Blood Culture in the Absence of Agglutination Reaction.—A Third Case of Influenzal Endocarditis Diagnosed by Blood Culture.—The Incidence of Spontaneous Cancer in Mice.—Observations on the Treatment of Lesions by Passive Congestion.—Method for Testing the Digestive Power of the White Corpuscles.

A MEETING of this society was held on Jan. 15th, Sir A. E. RIGHT, Vice-President, being in the chair.

Dr. T. J. HORDER read, in the absence of Dr. F. W. ANDREWS, his paper on Observations on MacConkey's Bile Salt Neutral Red Medium. The writer said that MacConkey had introduced culture media containing $\frac{1}{2}$ per cent. sodium taurocholate with neutral red and any desired carbohydrate as a means of differentiating between various members of the bacillus coli group. He had recently employed the agar medium which MacConkey recommended and had been much struck by its great utility not only in the study of the bacillus coli group but in the case of many other bacteria. He showed a number of plate cultures prepared according to MacConkey's formula and which contained a series of diverse carbohydrates and allied substances. These were as follows: the pentose, *isodulcitol* or *rhamnose*; the monosaccharide, *glucose*; the disaccharides, *saccharose* and *lactose*; the trisaccharide, *raffinose*; the polyatomic alcohols, *glycerine* and *mannite*; and the glucoside, *salicin*. He had selected those eight substances because they were amongst the most useful differential tests for members of the bacillus coli group. On the plates were to be seen growing six members of that group—namely, bacillus coli communis, the bacillus enteritidis of Gärtner, the typhoid bacillus, Schottmüller's two paratyphoid bacilli A and B, and Shiga's dysentery bacillus; also a typical streptococcus faecalis and two different staphylococci. All this had been done before by MacConkey, at least as concerned the bacillus coli group, though perhaps not with precisely the same series of test substances. Nevertheless, Dr. Andrews thought it worth while to show the cultures in case some members of the society might be unaware of the extent to which this valuable method of differentiation could be used and also because the explanation of the phenomena put forward by MacConkey, though they felt sure it was in the main true, did not quite cover all the facts. MacConkey regards the colour of the growth as essentially dependent upon the capacity of the given organism to ferment the given test substance, with the formation of acid, whereby a red colour was produced in the growth. In the majority of cases this certainly held good, but not in all. As regards the actual plates shown, it would be most convenient to consider the results organism by organism rather than plate by plate. In the following tables the results so far as concerned colour production on the plates, are set out with the results as concerned acid formation from the same chemical substance in litmus broth, both under aerobic conditions. Dr. Andrews had had to put in interrogation marks (?) here and there where the colour reaction was not

+ = formation of acid; ? = no formation of acid (formation of gas disregarded).

decisive. It would be seen that while there was a very striking, broad, general correspondence between the two sets of reactions there was by no means identity. Thus in the case of bacillus coli communis identity was complete save in the case of salicin. This body was readily fermented by the strain of bacillus coli employed, yet there was no red colour at all on the bile salt plate. In the case of Gärtner's bacillus there was practically complete identity, though in the test tube this organism partially fermented raffinose. Paratyphoid A grew beautifully red with glycerine on the bile salt plate but failed to ferment glycerine in the test tube and the same was true of paratyphoid B. With the typhoid bacillus the identity of the two sets of reactions was complete. Streptococcus faecalis, on the other hand, was colourless with glycerine on the bile salt plate, though readily fermenting it in the test tube, and it gave very feeble colouration with isodulcitol on the plate, though it could easily ferment this substance. The two staphylococci tested both fermented lactose equally well. Yet on bile salt neutral red lactose agar staphylococcus aureus formed no colour at all, whereas staphylococcus epidermidis albus grew bright crimson. It was therefore clear that there was some other factor concerned than mere ability to ferment the test body with formation of acid, though what this was Dr. Andrews did not know. The reactions in litmus broth which he had given were all carried out aerobically so as to be comparable with the plates. They did not in all cases correspond with those given by MacConkey, which were carried out anaerobically. But although one could not as yet explain all the facts, it was evident that these media afforded a wide choice which might be of considerable service in the search for any given organism of known reactions. And this field of usefulness extended beyond the limits of the bacillus coli group. He had tested a number of streptococci and had found that the sodium taurocholate inhibited the growth of streptococcus pyogenes, whereas the common faecal streptococci grew readily and with many of the test bodies

Sir A. E. WRIGHT demonstrated (a) a method for testing the tryptic activity of leucocytes and the antitryptic power of the serum, and (b) a method for measuring that tryptic power for clinical uses. A known quantity of blood was drawn from the finger and diluted with four parts of blood-saline and sterilised distilled water. From this a pellet of clot separated which inclosed all the white cells. The red blood corpuscles and serum were now washed away. Four tubes were then prepared; to all of these gelatin was added and to two of them serum was also added. After the tubes have been incubated, most conveniently at 37° C., for two to three days, in the former, digestion of the clot and of the gelatin took place; in the tubes, however, to which the serum had been added, no digestion occurred, proving that serum had some antitryptic action. In order to estimate the amount of tryptic action the following method was adopted. Known quantities of corpuscles and of albumin were taken into a capillary tube with varying dilutions of serum. In the mixture with pure serum no digestion took place. As the serum was further diluted more and more digestion took place, so that in the mixture which contained no serum complete digestion occurred. Such a method formed a means of estimating the tryptic action of any substance.

CLINICAL SOCIETY OF LONDON.

Acute Pneumonia with Abscess of the Lung and Acute Endocarditis.—Myxœdema with Changes in the Parathyroid Glands.—The Connexion of Tetany with Dilated Colon in Children.

A MEETING of this society was held on Jan. 11th, Mr. H. H. CLUTTON, the President, being in the chair.

Dr. FRANCIS H. HAWKINS (Reading) read notes of a case of Acute Pneumonia with Abscess of the Lung and Acute Endocarditis. The patient was a man, aged 51 years, who presented signs of pneumonia of the upper lobe of the right lung. After the temperature had been normal for a few days it gradually rose for ten days, then suddenly went up to 105° F. and fell to 102°, when the patient broke out in a profuse perspiration. On the following day he had a rigor and the temperature rose to 104°, then fell to 98°, and he again perspired profusely; two days later the patient became comatose and died. At the necropsy the right upper lobe was in a state of grey hepatization; it contained three abscesses varying in size from that of a walnut to that of a hen's egg; all were lined with a distinct lining membrane. At the base of the aortic cusp was a recent fibrous deposit which on being removed showed an ulcerated surface. No murmur had been heard during life. Dr. Hawkins pointed out the rarity of abscess as a complication in acute pneumonia. He regarded the case as one of endocarditis pneumoniae, and mentioned that Weichselbaum had demonstrated the diplococcus pneumoniae in a growth on the cardiac valves in similar cases.—Dr. O. THEODORE WILLIAMS commented on the suddenness of onset of abscess of the lung in such cases and the invariably fatal issue. There was no time, even if the other indications were favourable, for surgical intervention. Happily the complication was a rare one; he could only recall about four cases. In one of these, a woman about 60 years of age, large quantities of pus had been expectorated.—Dr. HAWKINS, in reply, wished to emphasise the fact that the expectoration was not purulent in his case; it was ordinary pneumonic sputum.

Dr. DAVID FORSYTH read a paper on a Fatal Case of Myxœdema with Changes in the Parathyroid Glands which will be found at p. 154 in the present issue of THE LANCET.

Dr. F. LANGMEAD read the notes of three cases of children in whom Relapsing Tetany had been associated with Dilatation of the Large Intestine. Case 1 was that of a boy, aged six years, who between November, 1903, and April, 1905, was admitted five times into the Hospital for Sick Children, Great Ormond-street, under the care of Dr. A. E. GARROD, suffering on each occasion from an attack of tetany. Each attack was accompanied by the evacuation of yeasty pulaceous stools and distension of the abdomen. Abdominal examination revealed the presence of a large hollow viscus on the left side. All treatment was ineffectual until lavage of the large intestine by means of a rectal tube was resorted to, when on each occasion improvement leading to recovery was initiated. The last attack was complicated by fatal distension of the hollow viscus was seen to be

the sigmoid flexure which was very dilated and occupied the greater part of the left half of the abdominal cavity. It held about 13 ounces of fluid. Case 2 was that of a boy, aged three years and two months, who was admitted on May 10th, 1906, also under the care of Dr. GARROD, for his fourth attack of tetany. This proved to be accompanied, as in Case 1, by the passage of pulaceous motions and the presence of a large hollow viscus in the abdomen. Lavage was temporarily successful, but a month after admission diarrhoea and rapid wasting began and operative treatment was employed. Mr. W. A. LANE removed ten inches of dilated sigmoid flexure and at first the child became better. Death, however, occurred 12 days afterwards. Post mortem the remaining large intestine was found to be enormously dilated; the walls being thin and atrophic. No obstruction was present. Case 3 was that of a girl, aged two and a half years, who was admitted under the care of the late Dr. STURGES in June, 1884, for repeated attacks associated with abdominal distension and offensive undigested motions. She was an emaciated child and continued to waste and died from a terminal broncho-pneumonia. Post mortem the only lesion found except broncho-pneumonia was a dilated transverse colon. Dr. LANGMEAD also referred to a case reported by Dr. H. BATTY SHAW and Mr. H. T. MANT.¹ It was that of a girl who for four years had suffered from gastro-intestinal disorder, for 18 months had had abdominal distension, and for seven months repeated attacks of tetany. Thyroid substance had proved effectual when other measures had failed. By operation a general dilatation of the large intestine had been found. These cases formed a definite and apparently hitherto unrecognised group, to which four attributes were common: (1) obstinate relapsing tetany; (2) abdominal distension; (3) offensive unhealthy motions; and (4) a dilated large intestine. The disappearance of the tetany after the bowel was irrigated and its reappearance when accumulation of the characteristic faeces took place showed that it was due in these cases to toxic absorption from the bowel. This favoured the toxæmic theory of tetany in general. Malnutrition, which was present in these as in most described cases, probably acted by producing an unduly irritable nervous system.—Dr. H. G. TURNER discussed the possibility of recognising by an examination of the abdominal distension whether the sigmoid or the whole colon was dilated.—The PRESIDENT said that he had operated on two cases in adults in which tetany was not present. He discussed the operative measures advisable and declared himself in favour of preliminary drainage of the colon for a month or so before attempting resection.—Dr. GARROD considered it was impossible either in the child or the adult to distinguish between enormous sigmoid dilatations and other colon dilatations. In such cases the sigmoid often extended over the whole abdomen, whereas, on the other hand, colon dilatations might closely mimic an enlarged sigmoid in its physical signs.—Dr. LANGMEAD, in reply, said that he would group the sigmoid and colon dilatations together for this purpose as forming a single condition.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on Jan. 9th, Dr. J. W. BALLANTYNE, the President, being in the chair.—Dr. Frederick PORTER communicated a case of Acute Albuminuria caused by the pressure of a tumour on both ureters. The patient, a multipara, aged 34 years, first came under notice complaining of backache and pain in the right hypochondriac and lumbar regions for five years. A tumour with the characteristics of a large moveable kidney was palpated in the right hypochondrium. Several months later the patient developed acute albuminuria with severe œdema of the whole body. Examination showed that pain was now referred to the right iliac region and a tumour was palpated in that region. On operation a multilocular cyst attached to the broad ligament and pressing on the ureters was found and removed. The albumin disappeared from the urine in nine weeks. The patient is now four months pregnant and is taking a light mixed diet.—Dr. Elizabeth H. B. MACDONALD (Dundee) read a paper on Intractable Uterine Hemorrhage and Arteriosclerosis of the Uterine Vessels. The paper was illustrated by 30 micro-photographs. Dr. Macdonald said: Many cases of severe uterine hemorrhage occurring near the menopause without obvious cause have been reported within recent years. By many observers, Reinecke, Chalmers, Pichesin and Petit, Pozzi, and more recently Barbour, the vessel changes

formed a bright crimson growth. This fact confirmed the opinion which he had elsewhere advanced as to the specific difference between these organisms. In the case of the staphylococci the media would prove of similar utility.

Dr. HORDER read a paper on a case of Typhoid Fever Diagnosed by Blood Culture in the Absence of the Agglutination Reaction. He said that recent observations made upon patients suffering from typhoid fever showed that the bacillus could be cultivated from the blood in a considerable proportion of cases. A single case of successful blood culture would not, therefore, deserve the notice of the society were it not that the case had some points of special interest. The patient, a young man, aged 27 years, was taken ill on Nov. 27th, 1906. Seen in consultation on Dec. 3rd, the eighth day of the disease, the chief clinical features were high continued fever (103-4° F.), headache, active delirium, and slight general bronchitis. The presence of a urethral discharge had suggested the possible existence of gonococcal blood infection. There was, however, no arthritis or any evidence of serous membrane inflammation. Films made from the urethral pus showed the presence of gonococci. A leucocyte count resulted in the discovery of a leucopenia, the white cells numbering 1400 only. A blood culture was undertaken at the same time. The leucopenia suggested that the disease might be typhoid fever. The agglutination test was therefore performed, with the result that a 1 in 20 dilution of the blood gave a few small clumps at the end of an hour. A 1 in 40 dilution gave no clumping at the end of an hour. As it is usually held that considerable dilution of the blood is necessary to obtain growth of the typhoid bacillus two of the broth tubes used in the blood culture were added each to 50 cubic centimetres of broth. In 24 hours there was no visible growth in either of the tubes, but in 48 hours a fluffy growth appeared in the blood-clot of two broth tubes which had not been diluted and the two diluted broth tubes showed uniform turbidity. In the blood-agar tubes, where the blood had received no dilution at all, good growth also appeared. On examination all the tubes showed the presence of an organism resembling the typhoid bacillus and it was found that this organism was clumped completely and rapidly by a dilution of 1 in 80 of the blood from each of two convalescing typhoid patients. In the course of the next few days classical reactions were obtained by use of the customary tests. The patient developed rose-spots eight days after the blood culture. The points of interest in this case were: (1) the early diagnosis of the case; (2) the demonstration of the bacilli in the blood in the absence of Widal's test; (3) the coexistence of a marked leucopenia with a large number of bacilli in the systemic blood-stream; and (4) the facility with which the organism grew without having recourse to high dilution of the medium or to the addition of such substances as ox-bile, &c. It might be that in this particular case the bactericidal power of the blood for the typhoid bacillus was exceptionally low. And the absence of the agglutination test might itself have been evidence of feeble immunity on the part of the patient.

Dr. HORDER related a Third Case of Influenzal Endocarditis diagnosed by Blood Culture. Last year he read a paper before the society in which he described two cases of ulcerative endocarditis due to Pfeiffer's bacillus influenzae. A pure culture of the bacillus was obtained upon more than one occasion from the blood of each patient, and in both cases post-mortem observations confirmed the existence of this organism in the heart-valves and the absence of other organisms. Dr. Horder suggested at the time that the occurrence of Pfeiffer's bacillus in association with ulcerative endocarditis would probably be found to be not uncommon. He was able that night to report a third case of endocarditis in which a pure culture of the bacillus influenzae was obtained from the patient's blood. The patient was a man, aged 50 years, admitted to St. Bartholomew's Hospital, where he was under the care of Dr. Samuel West. He had had rheumatic fever when 23 years of age. The onset of his fatal illness was insidious and its probable duration was about four months. The clinical picture was that of a chronic case of ulcerative endocarditis and there was nothing to suggest the nature of the causal organism. The technique of the blood culture was that previously described. In each of four broth tubes, as well as upon two agar slopes, minute colonies appeared in 24 hours and these were large enough to count in 48 hours. It was estimated that there were no fewer than 50 colonies present in each cubic centimetre of blood. The organism

obtained showed several of the features noted in Dr. Horder's previous paper. Thus, the members examined in the original blood-broth tubes were highly coccoid in form, and when seen as definite short bacilli they presented a bipolar appearance so frequently that casual observation might have passed the film as being that of a short streptococcus. Again, first and second subcultures were obtained without the addition of blood to the medium and the colonies on agar were at first opaque. Third subcultures, however, gave the characteristic dewdrop-like colonies. Gram-staining was readily and persistently negative in all colonies examined. Unlike the two cases previously described, this patient's leucocytosis was low—10,000, resembling what occurs most often in cases of chronic streptococcal endocarditis. Death occurred rather suddenly two weeks after the blood culture had been undertaken. A post-mortem examination was not obtained. In view of the present difficulties in satisfactorily assigning the exact rôle played by Pfeiffer's bacillus in the causation of influenza the occurrence of these cases of chronic septicaemia due to this organism obtains additional importance. That it is possible for the blood stream to swarm with any organism and for the patient meantime to be comparatively free from acute symptoms is one of the problems of immunity. That this organism is occasionally Pfeiffer's bacillus influenzae would appear to raise a serious difficulty in accepting the bacillus as the sole primary agent in the disease clinically known as influenza.

Mr. F. W. TWORT gave the following facts in relation to the Incidence of Spontaneous Cancer in Mice. He said that during the past two and a half years he had kept a large number of mice; during the first year out of some 100 mice no case of cancer occurred. During a subsequent period of 18 months out of some 120 mice 20 cases of cancer had occurred. One of these was a primary carcinoma of the lung and another was primary carcinoma at the junction of the stomach with the duodenum. Secondary deposits were present in the glands. This growth occurred in an old male mouse. All the remaining animals affected were females. Around many of the growths sarcomatous nodules were found in considerable number. He considered that this large incidence of cancer among mice was unusual, for he had kept mice for many years previously and had not seen a case in which a cancer visible to the naked eye was present.—Dr. W. BULLOCK said that the proportion of mice affected was much higher than he had met with in the mice kept in laboratories; on the other hand, only young mice were usually kept, whereas Mr. Twort had kept older mice.—Dr. E. F. BASHFORD said that the proportion of cases affected was undoubtedly high. Among 20 descendants of two mice which had cancer in only three was cancer present.

Dr. J. H. WELLS gave the results of some Observations on the Treatment of Lesions by Bier's Method (Passive Congestion). He said the treatment depended on two factors: (1) the increased supply of blood to the part; and (2) the presence in the blood of a substance with a high bactericidal power. Bier's method was to produce passive congestion by applying an elastic bandage on the proximal side of the lesion. In the first case, lupus of the elbow, the bandage was applied for an hour. The opsonic index, which before the application was 0.7, rose after removal of the bandage to 1.2 to 1.4; the same effect was noted on a second occasion. In the second case, tuberculous synovitis of the knee of nine months' duration, the opsonic index before treatment was 0.9; the bandage was applied for three hours and the index rose to 1.2. In a third case a similar effect was produced. In two other cases with external wounds the same treatment was adopted. A similar rise in the opsonic index was shown, but the lymph which exuded from the ulcer showed a falling opsonic index. The opsonic curve in these cases corresponded closely with the curve seen after artificial inoculation and after massage, and it was suggested that passive congestion had the same effect as these other two methods—raising the opsonic index by auto-infection.—Dr. R. W. ALLEN called attention to the fact that he had shown that the plasma obtained from muscle gave a much higher opsonic index than blood serum, and he attributed the good results obtained from massage to the fact that muscle plasma passed into the general circulation.—Sir A. E. WRIGHT doubted if the rise in the opsonic index after massage could be attributed to muscle plasma, for massage gave in the first place a negative phase, whereas if the raised opsonic index were due to the muscle plasma the rise of index should occur at once.

Reviews and Notices of Books.

Pathology, General and Special, for Students of Medicine.
By R. TANNER HEWLETT, M.D. Lond., M.R.C.P. Lond.,
D.P.H. R.C.P.S. Lond., Professor of General Pathology
and Bacteriology in King's College, London; Lecturer
on Bacteriology, London School of Tropical Medicine;
Physician to the Seamen's Hospital, Greenwich. London:
J. and A. Churchill. 1906. Pp. 540. Price 10s. 6d. net.

Professor Hewlett's book is primarily intended for the use of students and practitioners of medicine and in the preface we are informed that this object has throughout been kept in view; in other words, that the essentials of general and special pathology, with special reference to their bearing upon the art of healing, have been detailed. We may at the outset congratulate the author upon the successful manner in which he has carried out his intentions, for the subject matter is carefully arranged and concisely presented and very few important considerations have been omitted; indeed, it is rather a matter for surprise that he has been able to compress so large an amount of useful and up-to-date information within such comparatively small compass, the more so that his book is readable and is not a mere catalogue of facts and theories. A great deal of recent work has been succinctly summarised and incorporated in the text, and in cases where a detailed discussion of problematical matters or a minute presentation of the latest results is outside the scope of the work references are given in footnotes to important monographs or to papers with bibliographies. These references, being very carefully chosen, serve to enhance the value of the book considerably.

The first eight chapters are devoted to general pathology and the consideration of the chief pathological processes which are in all cases intelligibly described and carefully discussed. In cases where various explanations or theories have been propounded these are usually presented in a clear and concise manner and the balance of evidence is indicated. The scope and objects of pathology are first outlined and the causes of disease discussed with reference to their pathological significance. A chapter (No. II.) is devoted to the progressive and retrogressive changes. The processes of hypertrophy, hyperplasia, and regeneration are described. The various necroses, degenerations, and infiltrations are next discussed and the current views of their origin and significance are indicated. In the chapter on Neoplasms the various forms of new growth are briefly described and the recent important work on the cytology of malignant tumours is given in some detail; there is also an account of several of the theories as to the genesis of tumours. The description of inflammation is clear and concise, the vascular changes associated with it are described in greater detail than those of the tissue cells, while the process of suppuration might also with advantage be given in greater detail. The pathology of infection and of parasitism is given in Chapter V. The various organisms are described, their biological characters are given, and the lesions produced by them are outlined. The complex problems of immunity are dismissed with but short consideration, although reference is made to Ehrlich's side-chain theory, to Metchnikoff's doctrine of phagocytosis, and to the occurrence of opsonins as described by Wright and Douglas. A useful chapter is that devoted to fever and pyrexia; the changes in fever, the disorder of metabolism, and the varieties of fever are described, while the theories of the nature of fever are given at considerable length and critically examined. In like manner oedema and dropsy are carefully presented and the results of recent experimental work are given and applied to the discussion of the theories of oedema formation.

The remainder of the book is devoted to special pathology, the diseases of the various systems and organs being considered. Here the limitations of space are more apparent, for many important conditions are discussed with little more than passing reference. Curiously enough, some of the rarer conditions are given more importance than some of those of more common occurrence; for example, the account of achondroplasia extends to nearly two pages, while to pleurisy is accorded barely a page. Some of the chapters in this part of the book are, however, highly commendable, among which we may mention that on disorders of metabolism, where among other things the pathology of gout and diabetes mellitus is given, and that on diseases of the urinary system where the problems concerned in albuminuria and uræmia are carefully considered. Asthma and emphysema are well discussed, diseases of the pancreas receive considerable attention, and the results of recent researches are briefly summarised or references are given to them. In general, Professor Hewlett's accounts of pathological processes and his discussion of hypotheses or theories are better than the descriptions of the pathological anatomy of some of the tissues and organs, which are often meagre and incomplete, and might with advantage be lengthened in a subsequent edition. The only illustrations are those of microscopical appearances, and these are mostly reproductions of micro-photographs, most of which are satisfactory and illustrate the histological details of some of the conditions described.

This book should prove of value to the student. Taken in conjunction with a study of morbid anatomy in the post-mortem room, and of morbid histology in the laboratory, it should afford him a useful acquaintance with some of the fundamental facts of pathology without which a rational study of medicine is impossible. We can commend it as a useful elementary text-book on the subject.

Problems in Animal Metabolism. By J. B. LEATHES, M.B., B.Ch. Oxon., F.R.C.S. Eng. London: John Murray. 1906. Pp. 205. Price 7s. 6d. net.

THIS work represents a course of eight lectures delivered in the physiological laboratory of the University of London in 1904. Perhaps their scope is best set forth by giving the titles of the lectures: Physiological Chemistry and Metabolism; Assimilation and Syntheses of Carbohydrates; Catabolism of Carbohydrates; Assimilation and Syntheses of Fat; Catabolism of Fat; Assimilation and Syntheses of Proteids; Catabolism of Proteids; and Metabolism of Cyclic Formations. The last lecture is one of the most interesting of the series, as it deals with guanidine, kreatine, arginine, histidine, the purin bases, uric acid, and tyrosine, and their allies in the metabolism of the body.

These lectures are intended to point out that the study of animal metabolism is daily becoming less the study of the sum-total of chemical change in the body and more the study of the individual chemical reactions, the items that go to form the final sum. However simple and comprehensive the term metabolism—a word coined by Schwann—it includes some of the most intricate and inaccessible of natural phenomena. The ideal goal of physiological chemistry is still a long way off, but in these lectures we have for the thoughtful student an excellent representation of what has been done up to the present in this difficult department of study. In no department, perhaps, has the progress effected been greater than in the chemistry of the carbohydrates; indeed, the chemistry of the carbohydrates has become a problem in geometrical permutations, and most of the possible permutations have been identified and most of these synthesised. Even the colour tests for proteids—long nothing but empirical tests—have provided a means, when rightly studied, of throwing light on the constitution

have been regarded as the causal factor. Theilhaber, believing the vessel changes in many of the cases to be merely physiological, lays stress on the part played by the musculature, and Palmer Findley has recently supported him enthusiastically in this view. Anspach (1906) has demonstrated the physiological increase in elastic tissue in parous uteri, and suggests that hæmorrhage in some cases may be due to failure in the normal elastic increase. Another class of observers has sought the cause in ovarian changes. From a consideration of the mode of occurrence and control of normal menstrual hæmorrhage, the possible causes of abnormal hæmorrhage may be deduced. They fall naturally into three groups: (1) abnormalities in the periodic ovarian stimulation; (2) conditions giving rise to muscular insufficiency, either from actual deficiency of muscular tissue or loss of tone and consequent deficient response to vaso-motor stimulation; and (3) conditions giving rise primarily to continued congestion of the endometrium, either from increased arterial supply or venous obstruction. The first group has possibly more significance than is generally accorded to it. In considering cases coming under the second heading of muscular insufficiency the vessels are to be regarded as essentially part of the uterine musculature. The uterus may be ideally considered as a muscular expansion of its vascular walls, as Keiffer has pointed out. The third group is important and probably includes most of the cases of hæmorrhage becoming evident at the menopause. The vascular changes in the uterus, physiological and pathological, require special consideration. There is a definite increase in elastic tissue in the vessel walls and throughout the uterus generally with every pregnancy. Periarterial and perivenous degeneration, the degenerated areas showing a deposit of elastic tissue, is normal in parous uteri. This is shown in a case where the uterus was removed for severe menstrual pain, interstitial fibromyoma being suspected, but only a glandular endometritis being found on examination. Premature senile changes associated with alcoholism are demonstrated in a case where the symptoms pointed to cancer of the body of the uterus and where at operation the palpable tumour was found to be a sigmoid cancer and the uterus to be small and senile but otherwise apparently normal. Somewhat similar vascular changes are found in a case where there had been severe menorrhagia for ten years. The association of uterine arterio-sclerosis with general arterio-sclerosis is shown in a case with a history of syphilis. Here the vascular changes present peculiar features; no typical periarterial degeneration is found. The degenerated areas within and surrounding the vessel walls are composed of a more or less degenerated fibrous tissue and show no elastic deposit; at the same time there is a definite increase in elastic tissue in the interior of the larger vessels. The question is whether there is an arterio-sclerosis of the uterine vessels apart from that brought about by physiological causes. If so, will the condition necessarily be accompanied by hæmorrhage? Westphalen and Thoma have endeavoured to show that the peculiar vessel changes in the uterus are essentially due to the changes in the blood pressure to which the functioning uterus is subject. The periodic increase in blood pressure at the menstrual periods, and still more the pressure changes incident to pregnancy and the puerperium, cause changes in the uterine vessels to which no other vessels in the body are subject to the same extent. The uterine vessels, so to speak, are shorter lived than any others. If, now, it is supposed that changes in blood pressure in these arteries arise from some pathological condition similar changes will presumably occur. The changes in the vessels due to physiological processes cannot be regarded as causes of hæmorrhage. They may go to an extreme degree without the occurrence of any abnormal bleeding. This is only natural. Further, since these changes are essentially due to changes in blood pressure associated with the functioning uterus, they are possibly indistinguishable from changes due to a pathological increase in blood pressure. In the causation of hæmorrhage the important thing is the condition which gives rise to the vessel changes. To speak of arterio-sclerosis as the cause of the hæmorrhage is a mere confounding of words. The hæmorrhage is a symptom of the condition of which the arterio-sclerosis is a sign. If the conditions leading to arterio-sclerosis exist, hæmorrhage may occur before the vessel changes. At the opposite extreme are those cases where the changes have extended to the vessels of the endometrium and where the

F. W. N. Haultain, Dr. J. Ritchie, Dr. J. M. Munro Kerr (Glasgow), Dr. W. Fordyce, Dr. B. P. Watson, and Dr. Porter discussed the paper and Dr. Macdonald replied.

SOUTH - WEST LONDON MEDICAL SOCIETY.—

A meeting of this society was held on Jan. 9th, when a paper was read by Mr. Charters J. Symonds on the Diagnosis and Treatment of Malignant Disease of the Cæcum. Mr. Symonds related a series of cases, which he illustrated by preparations, drawings, and lantern slides, showing the varieties of the clinical histories which were presented and the difficulties which lay in the way of accurate diagnosis. In most cases colic was a predominant feature and the recurrence of colic indicated the necessity of a careful abdominal examination as a matter of routine. Colic was not, however, invariably present, as shown by a patient who came for treatment on account of a tumour in the right iliac fossa which had been discovered by herself although giving rise to no symptoms. The differential diagnosis from chronic appendicitis was of the greatest importance, as an error that might involve the postponement of operation was fatal. The pathognomonic distinction lay in the mobility of the tumour in early stages, whereas appendicular masses being inflammatory were always fixed. More rarely tuberculous ulceration of the cæcum or enlargement of glands in the ileo-cæcal angle might give rise to difficulty in diagnosis. Age was of no value in forming an opinion; he had operated on patients as young as 34 and as old as 75 years. The treatment that could alone be effective was by operation and the method adopted was the removal of a portion of the ileum and of the ascending colon and the lateral anastomosis of the former into the latter. The glands of the mesentery were removed as far as possible, involving in some cases a difficult and protracted procedure. The results had on the whole been most successful. The conditions under which an operation should be undertaken were considered; it was a question whether the presence of serum was not a bar to successful operation as it appeared probable that serious symptoms had followed in one case which were attributed to the collection of serum in the cavity left by operation; in this patient a rapid infection of the wound by the growth had taken place. The involvement of coils of intestine did not necessarily require the abandonment of the operation; such involved coils might be separated or even resected. The condition of the patient as to pallor and wasting had to be taken into consideration and much judgment was needed in forming an opinion, as they might proceed from small and repeated hæmorrhages, or from septic absorption, or from the cachexia of malignancy. In the two former an operation might be performed without hesitation. Mr. Symonds urged the wisdom of early operation, pointing to the good results which ensued. He deprecated too light an estimation of the nature of a tumour because it was moveable, or of long duration, or existent in a patient apparently in good health. He held that at present no limits could be placed to the extent of an operation provided that all diseased structures could be removed.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—

A clinical meeting of this society was held on Jan. 4th, Dr. L. P. Mark, the President, being in the chair, when the following cases of interest were shown: Mr. D. J. Armour showed: 1. A man, aged 70 years, with an Epithelioma on the Alveolar Border of his Upper Jaw. His teeth were in a very bad condition and a jagged stump on the lower jaw exactly fitted into the excavation formed by the growth on the upper jaw. 2. A young man from whom he had removed a large Endothelioma from the Left Frontal Lobe weighing three and a half ounces. It was apparently growing from the falx cerebri and was enucleated without much difficulty and the patient made a perfect recovery.—Mr. Aslett Baldwin showed two sisters, one aged three and a half years and the other 11 years, with Bilateral Congenital Dorsal Dislocation of the Hip and the typical waddling gait. The trochanters could be drawn down a considerable distance in the younger child but only to a slight extent in the elder one. Mr. Baldwin thought the younger patient could be greatly benefited by a combination of Lorenz's operation and opening the joint from the front to make sure that the front part of the capsule was freed from the floor of the acetabulum.—Mr. E. P. Paton showed a man with Multiple Perforating Ulcers and marked signs of locomotor ataxy.—Mr. J. G. Alder exhibited a Growth in the Neck treated by the x rays. A microscopical examination showed the growth to be composed of many giant

therapeutics it would seem that serum treatment proper is of but limited use, more being accomplished by protective vaccination against infective conditions. A long list of diseases is attributed to the action of infective agents so small as to be invisible even under the highest available powers of the microscope; this includes rabies, variola, and foot-and-mouth disease, all of which may affect mankind, as well as the epizootics, bovine contagious pleuro-pneumonia, rinderpest, and South African horse sickness. Probably swine fever and canine distemper are also due to invisible organisms. Quite a considerable number of epizootic diseases are due to protozoan organisms; such are Texas fever, red-water fever, equine biliary fever, and canine malignant jaundice, all of which are technically piroplasmoses; and several forms of trypanosomiasis, such as surra and nagana. Spirochætae—whatever may be the true biological position of these organisms—cause disease in geese and fowls, while the author has found them invariably present in cases of canker and grease in horses. Many other points of interest are contained in the book before us, which is also adequately illustrated. We are sure that it will be appreciated by those for whom it is intended.

LIBRARY TABLE.

A Text-book of Botany for Secondary Schools. By J. M. COULTER, A.M., Ph.D., Head of the Department of Botany at the University of Chicago. London: Sidney Appleton, 1906. Pp. 365. Price 5s. net.—This book is based upon some previous works of the author who has availed himself, as he states in the preface, of the opinions of many experienced teachers of botany. The book is divided into 25 chapters. Commencing with a description of the structure, function, and relationship of plant organs the author goes on to describe the various divisions of the vegetable kingdom and gives a short account of plant breeding and forestry. The four concluding chapters are devoted to "plant associations" or the way in which plants become grouped together according to conditions favourable to their growth. Those who are familiar with the author's previous works will be prepared to hear that the present text-book is an excellent one, and it is made the more valuable by being the outcome, as we have already said, of the co-operation of the author and other teachers. Practical work is insisted upon, the author emphasising the need of the supplementary aid of the teacher, the laboratory, and field work. Used in this way the book will be found of great value, while the style and plan of the work also make it suitable for general reading, and the clearly printed illustrations, of which there are 320, greatly elucidate the text.

War with Disease, being a Series of Lectures on Preventive Medicine delivered to the Officers and Non-Commissioned Officers of the Cavalry Brigade in Ireland under the Command of General M. F. Rimington, C.B. By FREDK. F. MAC-CABE, M.B. Dub., Medical Officer of the South of Ireland Imperial Yeomanry. Dublin: Doland, Limited, naval and military printers, 1906. Pp. 78. Price 6d. net.—Although of no great size, this book contains a mass of information set forth in so admirable a style that if the truths embodied in it are borne in mind epidemic diseases peculiar to an army in the field should have their power for evil vastly reduced. General Rimington has written an excellent introduction addressed to his men, after which the work opens with the subjects of the physiology of the blood and digestion, and of the bacteriology of the diseases incidental to soldiers. The remarks on the water-supply of troops are excellent and the author gives a telling instance in his own person of how a medical officer can influence the minds of soldiers and cause them to take the necessary precautions against enteric fever and dysentery. He contrasts

the returns of the deaths from disease in our South African War with those which occurred among the Japanese in their war, much to our disadvantage. Lecture II. deals with diseases of the lungs and zymotic and venereal affections. His remarks on the preventive measures to be undertaken against the last class of disease are peculiarly apposite and, moreover, are quite up to date, as they include the most recent investigations of Dr. Roux and Professor Metchnikoff. In Lecture III. tropical diseases are considered. We are glad to see that the use of the "cold tub" as an exciting cause of disease in the tropics is insisted on. Malaria, yellow fever, Malta fever, tick fever, cholera, and dysentery all receive due attention. The last lecture is devoted to personal and camp hygiene. The work is replete with valuable hints for the combating of disease and has given us much pleasure in perusal.

1. *Examination Questions for the Diploma of Public Health.*

By HUGH R. JONES, M.D., D.P.H. Camb. London: Baillière, Tindall, and Cox, 1906. Pp. 96. Price 2s. 6d.—

2. *Five-figure Mathematical Tables for School and Laboratory Purposes.* By A. DU PRE DENNING, M.Sc. Birm., B.Sc. Lond. London: Longmans, Green, and Co. 1906. Pp. 22. Price 2s.—

3. *Elementary Science applied to Sanitation and Plumbers' Work.* By A. HERRING SHAW, Manchester: The Artistic Printing Co., Limited. London: The Sanitary Publishing Co., Limited. 1906. Pp. 234. Price 2s. 9d.—

As the subjects of these three small books have several points in common it will be convenient to consider them in one notice. 1. Dr. H. R. Jones has compiled a useful selection of about 470 examination questions arranged under 15 headings, of which the first five are Chemistry and Physics, Practical Bacteriology, Practical Microscopy, Practical Chemistry, and Sanitary Inspection. It is not a "cram book," as it does not give answers to the questions or hints or "tips" of any kind, but it supplies excellent material for practice or for self-examination by candidates before presenting themselves for the final ordeal. Two of the questions seem to us to be rather conjectural in their scope and therefore unsuitable for examination purposes. One of them (on p. 24), is "Give an account of atmospheric electricity and its influence on health"; the other (on p. 47) is as follows: "The death-rate from violence is increasing. Is there any probable explanation?" 2. Mathematical tables may be appropriately mentioned here, as the first question in Dr. Jones's treatise just referred to, is, "What are logarithms?" Mr. A. du Pré Denning's object is to exhibit the usual five-figure tables of anti-logarithms, logarithms, circular functions, squares and cubes, and so on, on pages of somewhat large size, their type surface being a close approximation to that of THE LANCET. This arrangement, as he points out, naturally requires less turning over of pages. Tables of atomic weights, differential coefficients, electrical units, and various numbers in frequent request are appended. 3. Mr. A. Herring Shaw's "Elementary Science" is primarily intended for students who may be preparing for the examinations of the Royal Sanitary Institute of Great Britain and for certain examinations open to plumbers. It is an excellent compendium of the information required for such purposes, is copiously illustrated, and contains numerous exercises and problems, fully explained and worked out, corresponding to many of the examples given by Dr. Jones in his "Examination Questions" under the headings of Physics, Air and Ventilation, Sewage, and Miscellaneous.

JOURNALS AND MAGAZINES.

The British Journal of Tuberculosis.—The first number of this new publication has now been issued. The object of the journal is to deal with the many medico-sociological problems which gather round tuberculosis, more particularly

of the proteid molecule and the same may be said of the products of gastric and pancreatic proteolysis. But even, when all is said and done, what we obtain is clearer views as to the composition and constitution of the material in which the chemical processes of life are carried on, and not that the chemical processes themselves are clearer for what has lately been accomplished in physiological chemistry. After all "no laboratory can rival an animal cell." The immense importance of ferment action is insisted on. We may recall the observation of Ludwig that physiological chemistry may some day prove to be a chapter in the chemistry of catalytic action. Indeed, the extension of the idea of enzyme action into all phases of metabolic activity has been to effect a revolution in physiological chemistry.

To appreciate fully the importance of the variety of problems set forth the reader should have a good all-round knowledge of physiology and in addition should be conversant with organic chemistry in its modern aspects and developments. Perhaps the student of medicine would find it advantageous in studying the problems of metabolism if he made a point of reading as an introduction the chapters on cognate subjects in "Recent Advances in Physiology and Bio-Chemistry," edited by L. Hill.

These lectures are most comprehensive and present a very explicit account in the English language of the subjects with which they deal.

Syphilology and Venereal Disease. By O. F. MARSHALL, M.D., M.Sc. Vict., F.R.C.S. Eng., late Assistant Surgeon to the Hospital for Diseases of the Skin, Blackfriars; formerly House Surgeon to the London Lock Hospital. London: Baillière, Tindall, and Cox. 1906. Pp. x-509, demy 8vo. Price 10s. 6d. net.

THE author reminds us that since the work on Syphilis and Local Contagious Disorders written by Berkeley Hill and Arthur Cooper appeared about 25 years ago there has been no book published in England dealing in a systematic manner with syphilis and venereal diseases. Of late much light has been thrown on the pathology of syphilis by the experimental inoculation of monkeys by Metchnikoff and Roux, Neisser, Finger, and others, and by the discovery of the spirochæta pallida by Schaudinn and Hoffmann; an account of the research work is found in Dr. Marshall's pages. The important subject of parasyphilis, the conception of which originated with Fournier; the more recent evidence with regard to the question of the transmission of syphilis to the third generation; the question of paternal heredity; the syphilitic origin of general paralysis; the etiological factor of syphilis in arteriosclerosis, aneurysm, Bright's disease, cirrhosis of the liver, epilepsy, and other disorders of the nervous system; and other problems in syphilology are sufficiently discussed in this book. The portion dealing with syphilis is based chiefly on the teaching of Fournier and his followers: that dealing with gonorrhœa on the writings of Finger, Neisser, Jadassohn, and Balzer. On controversial points the author gives his own opinions. He emphasises the importance of syphilis and gonorrhœa as etiological factors in disease. When it is remembered that they are probably the oldest diseases which afflicted mankind, that they are both very contagious, that syphilis is the most hereditary of all diseases, and that gonorrhœa is the cause of a large proportion of the diseases from which women suffer, it is, as the author says, "difficult to overestimate their importance."

In the historical survey of syphilis Dr. Marshall tells us that the disease appears to have been known among the Hindus 1000 years B.C. and, on the authority of Klein, he states that mercury was used by the Hindus for the treatment of syphilis. Dr. Marshall says that Zambaco found bones with apparently syphilitic lesions in the ancient necropolis of Cairo showing that syphilis probably occurred

among the Egyptians. According to Dabry the oldest evidence of syphilis is found among the Chinese. In 2367 B.C. the Emperor Hoang-ti collected the medical writings which were then existing, and these have been translated by Dabry who states that the Chinese were acquainted with syphilis and treated it with mercurial inunction, that they differentiated between syphilis and gonorrhœa, and that they recognised the hereditary transmission of syphilis. Dr. Marshall writes that the existence of syphilis in prehistoric times has been assumed by the discovery of human bones showing signs of syphilitic lesions. At Solutr , where prehistoric human remains have been found, a woman's skeleton was found with nodes on the tibia which were regarded as syphilitic by Virchow.

The section on the pathology of syphilis brings out all the points very clearly before the reader. The bacteriology, the experimental inoculation in apes, the experiments in serotherapy, and the questions of reinfection and of re-infection in hereditary syphilis are all thoroughly gone into and discussed in a most interesting manner. At pages 306 and 307 the author gives the details of his scheme for the treatment of syphilis; the whole treatment is by metallic mercury, in the form of pill, gray oil injections, or inunction. The main objection to this programme is the number of years over which the treatment is spread. The three sections on parasyphilis, which is, perhaps, better called quaternary syphilis, are most instructive reading. The author quotes Ferrier's suggestion that the terms cerebral tabes, spinal tabes, and cerebro-spinal tabes should be substituted for general paralysis, locomotor ataxy, and tabo-paralysis. In a most useful appendix are given the methods of staining the spirochæta pallida, the method of staining it in sections, and the methods of staining the gonococcus. There is also a list of the chief preparations of mercury used for mercurial injections, with the dose and percentages of mercury in each and of the chief substances used for injection in gonorrhœa. The author likewise gives details of Zittmann's treatment of chronic rebellious cases of tertiary syphilis. With regard to the treatment of gonorrhœa in the male the wise rule is laid down that the urethroscope should never be used in acute or recent cases of urethritis. It is especially indicated for simultaneous diagnosis and treatment and should not be passed an unnecessary number of times for purposes of diagnosis only.

The book is up to date and we congratulate the author on its appearance. The print and binding are good and it is illustrated with five plates which are arranged at the beginning and at the end of the volume.

Notes on Blood-Serum Therapy, Preventive, Inoculation and Toxin and Serum Diagnosis, for Veterinary Practitioners and Students. By WALTER JOWETT, F.R.C.V.S., D.V.H., formerly Demonstrator of Comparative Pathology and Bacteriology in the University of Liverpool. London: Baillière, Tindall, and Cox. 1907. Pp. 204; Price 5s. net.

So far as we are aware this is the first book published in this country dealing with the subject of serum treatment and vaccination as applied to veterinary medicine, and the author is to be congratulated upon his success in giving a fairly complete account of this branch of research. The study of comparative pathology may do a great deal to throw light upon dark problems in human disease and medical men may find food for reflection in much that is contained in this little book. For example, the facts ascertained as to the diseases of sheep known as louping ill and braxy reveal a curious relation of immunity to season of the year, animals being immune to each of these diseases for certain months, but the season of protection not being the same for both maladies. In veterinary as in human

THE LANCET.

LONDON: SATURDAY, JANUARY 19, 1907.

The Medical Inspection of School Children.

IN the closing days of last year we received the report of the Public Health Committee of the London County Council submitting the report of the medical officer of health for the county for the year 1905. This interesting volume, which is dealt with at p. 185 of our present issue, contains as one of its appendices the report of the medical officer (education) for the year ended March 31st, 1906, and this appendix has been issued as a separate report which now lies before us. In the summer of 1905 the London County Council appointed 20 local assistant medical officers or medical inspectors, who began their duty on Sept. 1st, 1905. The duty of these officers, in the words of the report, is "to visit the schools of one district, spending three school sessions weekly in such work and making a weekly report on the schools visited." The school session, we gather from another portion of the report, is half a day—a scholastic day, that is—so that three school sessions would be about ten hours, and on an average six sessions are devoted to each school—that is, about two sessions to each department—viz., boys, girls, and infants; but among the poorer classes sometimes as many as three or four sessions may be given to any one department. The first selection of the cases to be seen is made by the teachers, but, as the report states, it is obvious that only very marked cases of defect are likely thus to be noticed. The early stages of the disease are therefore not detected. Some teachers, we learn, regard the medical officers' work as inquisitorial, and a few of the non-provided school teachers object to the medical inspectors' visits. We note that the report points out the difficulty of following up the cases, a difficulty which must be obvious to anyone who has had any experience in medical work among the poor. One interesting feature of the report is the remarks upon the conditions of school buildings and surroundings with respect to lighting, ventilation, heating, sanitation, and furniture. As regards these important hygienic armaments the reports of the local assistant medical officers are divided into those dealing with provided schools and non-provided schools. As is only to be expected, provided schools come out far the best, but without wishing to embark upon a singularly embittered controversy we must point out that a provided school obtains all its money from the rates without difficulty, which is not the case with a non-provided school. To turn to some of the detailed reports, that dealing with dental conditions is interesting and at the same time somewhat painful reading. The percentage of caries is very high and this, together with alveolar

abscess, is a fruitful source of septic poisoning and chronic gastric disorder. 245 children examined at the Michael Faraday school had on an average 3·9 carious temporary, and 2·8 carious permanent, teeth each, while 9·3 per cent. had alveolar abscess or purulent fistulae. Another interesting feature of the report is the section dealing with the physically defective in ordinary schools. Out of an attendance of 14,098 children there were 105 cases who were physically defective and of these 31 were suffering from rickets. Ricketty children apparently come from a special class, the existence of which is due to the general want of appreciation of the hygienic needs of childhood by ignorant mothers. As Mr. N. BISHOP HARMAN is quoted as saying, "The children are of a respectable class. They are well fed and clothed, but are altogether a flabby and pappy lot. Almost all of them have palpable glands in the neck. The head teacher returned over 100 as defective. This seemed absurd until the children were examined. Then the oft-repeated note of 'delicate' was justified. The children are too respectable to play in the street. They have no near park or fields. Their back gardens or house-rooms are small, so that they do not compare favourably save in cleanliness with children in poorer quarters who play freely in the open air. The teaching of hygiene is needed in the district."

It is interesting to note that a medical examination has recently been made in Liverpool of three large council schools in that city and some results of the examination were given in the letter from our Liverpool correspondent in THE LANCET of Jan. 12th. To mention some other points not referred to by our correspondent these three schools are respectively representatives of three classes, A, B, and C—A being a type of the best class council school where the parents of the child were well-to-do; B, a school where the parents were mostly of the labouring classes or small shopkeepers; and C, a type of the poorest classes where the parents belong almost entirely to the employed or casual labour section. The medical inspector was Mr. A. S. ARKLE and we note that he mentions that the children in the poorest school—namely, C—come out more healthy than those of schools of the types A and B. Mr. ARKLE suggests that the children in C class mostly live out-of-doors and so are hardier than children who are rather better off, a conclusion which is curiously like that of Mr. HARMAN.

The question of medical inspection of school children is one of the utmost importance, not only in its present aspect as regards the health of the community now, but also when we look towards the future and think that in 20 years time those of our present scholars who are then alive will be full-grown subjects of the empire. On them in great measure will depend the prosperity of our country. The system of medical inspection has not as yet been at work in this country for a long enough period to enable conclusions of any real value to be drawn, but in Germany, at all events, the results are obviously valuable, and there the system has been at work for some years. The chief difficulty, of course, which medical inspection has to deal with is ignorance—that is to say, ignorance of parents, ignorance of teachers, and ignorance of children themselves. The ignorance of the teachers is gradually being abated but the ignorance of

the pulmonary variety. Tuberculosis is not only a puzzle in pathology but appeals to all sorts and conditions of men as a question of world-wide importance. As we have already indicated¹ the journal will be issued under the editorship of Dr. T. N. Kelynack and the contents of the first number demonstrate the keen interest taken in the matter by the leading authorities. After some able editorial remarks Professor T. Clifford Allbutt contributes a paper entitled "The Study of Tuberculosis: A Retrospect," in which he vividly sketches the lines upon which the treatment of the disease has been conducted hitherto and then gives a brief outline of the evolution of the hygienic treatment. This is followed by an article by Dr. R. W. Philip headed "An Anticipation," dwelling among other matters on State and municipal responsibility. Dr. Philip considers notification to be a sound and necessary measure, and is confident that compulsory notification must be appealed to for the ultimate solution of the problem of tuberculosis. He refers to the fact that the Local Government Board for Scotland has declared in favour of notification. The result of this action will be watched with interest. Several pages are then occupied by a "Discussion" on the care and control of the consumptive poor. This is opened by Sir Richard Douglas Powell who deals with the disease as occurring in England and Wales. He considers the subject of practical reform and its difficulties. He says that it must, in truth, be confessed that at the present time there are no adequate means of treating the poor afflicted with consumption. The village medical practitioner or out-patient physician may make an early diagnosis but not one-hundredth of the cases so recognised can be taken in hand for proper treatment. He urges that co-ordination of effort on the part of philanthropic and municipal bodies is essential. He considers, however, that to adopt compulsory notification is doubtfully justifiable whilst there are no means of fulfilling its logical corollaries. Sir Richard Douglas Powell's remarks are characterised by thoroughness and sound common sense and should be carefully considered by medical officers of health before recommending the adoption of compulsory notification. Dr. Byrom Bramwell continues the discussion, taking the disease as it is seen in Scotland and the measures which are proposed for its control. He also urges the necessity of a combined effort for dealing with the disease. Naturally, he has much to say on the rôle of the Local Government Board for Scotland in reference to compulsory notification. Dr. Bramwell is of opinion that such a measure is essential if a thorough and determined effort is to be made to grapple with pulmonary tuberculosis and other forms of tuberculous disease. None of the objections which have from time to time been brought against compulsory notification are, in his judgment, of any real weight. Voluntary notification seems to him to be merely a makeshift and a compromise. Sir John W. Moore discusses the control of the Irish consumptive poor and although he says but little about compulsory notification appears to favour it. He gives a brief account of the measures available in Ireland for the relief of tuberculosis among the poorer classes. Amongst the original papers may be noted one on Tuberculosis and National Efficiency, by Sir Lauder Brunton; and one on Climate as a Factor in the Treatment of Tuberculosis, by Sir Hermann Weber. Other contents are descriptions of certain institutions for the tuberculous, including the King Edward VII. Sanatorium at Midsbury, remarks on health stations, and reviews and notices of books. We congratulate the editor on the success of the first number and once more wish our new contemporary every success.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Jan. 10th, Mr. HENRY MORRIS, the President, being in the chair.

Some recommendations of the library committee for enlarging the library by alterations to adjoining rooms were approved and adopted.

Sir JOHN TWEEDY presented on behalf of Mr. Sidney Young a transcription of the Book of Ordinances dated 1435 of the Guild of Surgeons, with an illuminated frontispiece by Mr. Austin Travers Young. The following motion was carried:—

That the thanks of the Council be and are hereby given to Mr. Sidney Young, F.S.A., for his gift of a transcription of the Book of Ordinances dated 1435 of the Craft of Surgery of the City of London, and to Mr. Austin Travers Young for the illuminated frontispiece representing in proper colours the arms given to the craft by King Henry VII. in the year 1492.

Letters were read from Mr. W. Watson Oheyne and Mr. Frederic S. Eve resigning their seats on the court of examiners as from the completion of the pass examination in surgery commencing on Jan. 11th, in anticipation of the expiration of their period of office on March 20th. The PRESIDENT stated that the vacancies on the court of examiners occasioned by the resignations of Mr. Watson Oheyne and Mr. Eve would be filled at the meeting of the Council in February. Mr. Watson Oheyne does not propose to offer himself for re-election.

In reference to the letter from the Liverpool School of Tropical Medicine, asking the views of the College on the scheme for the extension of the course of instruction at the school, it was decided to state that the Council is of opinion that so far as the scheme relates to the subjects of tropical medicine, tropical surgery, and tropical hygiene it deserves approval. The Council notes with satisfaction that it is proposed to afford greater opportunities for clinical observation than exist at the present time.

Course of lectures for 1907.—The following are the arrangements for the annual course of lectures to be delivered at the Royal College of Surgeons. The lectures will commence on Feb. 4th and will be delivered on each Monday, Wednesday, and Friday, until March 22nd, with the exception that during the week in which the Hunterian festival takes place the course will be suspended.

Erasmus Wilson lectures.—Mr. Willmott H. Evans will deliver one lecture on *Leucoderma and Analogous Pigmentary Changes in the Skin* on Feb. 4th; Mr. Reginald C. Elmslie, one lecture on *Injury and Deformity of the Epiphysis of the Head of the Femur (Coxa Vara)* on Feb. 6th; and Mr. Kenneth W. Goadby, one lecture on the *Etiology and Pathology of Pyorrhea Alveolaris (Rigg's Disease)* on Feb. 8th. During the week following this lecture the Hunterian festival will be held, the course being resumed on the following Monday.

Arris and Gale lectures.—Mr. J. Faulkner Dobson (Leeds University) will deliver two lectures on the *Lymphatic System of Certain Portions of the Alimentary Canal*, on Feb. 18th and 20th, and Dr. Bertram L. Abrahams one lecture on *Some Clinical Applications of Physiology* on Feb. 22nd.

Hunterian lectures.—These lectures will be delivered by the following Hunterian professors: Mr. W. Sampson Handley, two lectures on the *Pathology of Melanotic Growths in Relation to their Surgical Treatment*, on Feb. 25th and 27th; Mr. J. W. Thomson Walker, two lectures on the *Renal Function in its Relation to Surgery*, on March 1st and 4th; Mr. J. Howell Evans, two lectures on *Cysts and Cystic Conditions of Embryonal Origin*, on March 6th and 8th; Mr. William Wright, three lectures on the *Prehistoric and Early Historic Inhabitants of England*, on March 11th, 13th, and 15th; and Mr. Cecil F. Beadles, who will conclude the course, has chosen the two following subjects for his three lectures to be delivered on March 18th, 20th, and 22nd: (a) *Anatomical Variations in the Larger Arteries of the Brain and their Medical and Surgical Aspects*; and (b) *Aneurysms of the Larger Cerebral Arteries with Special Reference to their Possible Diagnosis and Treatment*.

might be carried further, because alcohol goes on improving in quality long after five years, and 6d. per gallon per annum might be subtracted from the 11s. for a further period of three or four years at any rate. There is still one doubtful point that only practical experience is likely to clear up and this point our correspondent puts in the following question. Would the matter of mere cost always be the controlling motive? There are plenty of blended whiskies on the market to-day guaranteed to be three, five, or seven years old which contain spirit manufactured within the 12 months. Blenders contend that this is no fraud, because they add spirit of greater age than the guarantee and so make the average right. But even a little of the new spirit might carry with it unwholesome qualities, and a graduated tax ought to have excellent influence; if such a measure did not put an end to the practice the question could be considered of imposing absolute prohibition on spirit of less than a specified maturity.

Barmaids.

AMONG the many derelicts of the Parliamentary sessions of 1906, sacrificed, more or less, to political exigencies manifestly incapable of fulfilment, not the least important, in a social sense, was a Bill to restrict the employment of barmaids. We had occasion early last year to consider the bearings of this question at some length and in relation to a pamphlet in which the necessity for restrictive legislation was set forth; and we cannot but regret that this necessity was not brought under the notice of Parliament. It has been clearly established that the employment of young women as barmaids is in many respects objectionable, partly because it introduces them to an occupation which is seldom or never of a permanent character, partly because it often entails an amount of standing which is calculated to be injurious to health, and chiefly because it is attended with many temptations to drink and with many temptations to immorality. The temporary character of the employment depends, indeed, upon the obvious fact that young and good-looking barmaids are in demand as sources of attraction to the bars in which they are engaged; and that, as soon as they lose either their physical charms or a certain pertness which is perhaps incidental to the liquor traffic, they are liable to be dismissed in order to make room for successors who retain these characters. Even in the male sex, it is well known that employments for the young, which are not educative, that is to say, which do not afford opportunities for learning some definite form of industry, and which cast adrift, at early manhood, those who have been engaged in them, are of very questionable value to the community; and hundreds of boys, who have been tempted into such occupations by the prospect of good wages and temporary employment, have had only too much reason to regret their choice. In the case of women, with marriage to a bread-winner as a natural goal, the temptation to embrace a merely temporary calling is even greater than with men; and the results, when the matrimonial goal is not attained, are likely to be even more disastrous. Even under the best conditions, the industry of the bar is but little calculated to be a preparation for discreet wifehood and motherhood, or for the nurture of children calculated to add to the physical and

moral strength of the community. The barmaid is liable to be brought into intimate association with worthless and intemperate people, to be morally contaminated by much that she is compelled to see and hear, and to be forced to sacrifice her own sense of modesty and propriety to the demand of her employer that she shall make herself agreeable to his customers.

In these circumstances, there can be little doubt that legislation is required in the interests of the class of women more immediately concerned, or that such legislation would be regarded favourably by the public; but it is at least equally certain that it should be governed by careful consideration of all the consequences likely to be produced. The derelict Bill to which we have referred provided that, from the time of its enactment, no woman should enter for the first time upon the duties of a barmaid, and that only those should be permitted to continue in the employment who had already been so occupied for at least three months. A register of existing barmaids was to be constituted and placed under the control of the licensing justices and of the police, and licensed persons were to be prohibited, under heavy penalties, from employing in the capacity any women whose names were not upon this register; so that, as these women ceased, from various causes, to be available, the class to which they belonged would cease to exist. So far, the provisions of the Bill were reasonable, inasmuch as they would entail no hardship or loss of employment upon women already committed to the industry, and, indeed, would be calculated to increase their value; but here the reasonableness ends. The Bill further provided that nothing in its contents should prevent the wife or daughter of any licensed person from being employed as a barmaid upon the premises of such licensed person, and then subjected this provision to the condition "if the justices permit"; while a previous clause would give power to the justices, on the occasion of the annual renewal of any licence, to impose the condition that no barmaid should be employed on the premises, and, if the licensed person should refuse to assent to or should violate this condition, would allow the justices to refuse without compensation the renewal of the licence. In other words, it was gravely proposed to permit the daughters of publicans to serve as barmaids upon premises occupied by their parents and thus to engage in a form of industry deliberately condemned by the legislature as unfit for respectable women, while, on the other hand, it was proposed to subject the parental discretion in the matter to the absolute and irresponsible control of the licensing justices of the particular district concerned. There can be no doubt that under such a law the question whether the daughters of publicans should serve in their father's or mother's bars would be made a party one in many localities, and that the decisions of the justices upon the point would be governed by many considerations wholly irrelevant to the real merits of the case. The suggestion to admit parental responsibility as a general principle and then to override this responsibility by the decision of a casual bench of magistrates is equally inconsistent with liberty and with common sense. If it be improper to employ girls as barmaids, the impropriety is not diminished by the fact that they are the daughters of publicans; and no question which falls rightly under

parents will take many years to overcome. Take, for instance, the case of measles. The average parent has no idea that in by far the majority of cases the dangerous time for the child is not while the rash is out but after it has disappeared. Over and over again we have known parents in deliberate disregard of their medical attendant's advice let their children go out to sit on a cold doorstep directly the measles rash has disappeared, with the almost inevitable result that bronchopneumonia supervened. Teachers can be, and are, taught simple hygienic rules. To teach the parents is extremely difficult, if not impossible under present conditions, but unless medical inspection of schools can include some method of making parents obey some of the simpler rules of hygiene its benefits, great as they are, will be but a tithe of what they might be.

The Control of the Sale of Potable Spirits.

WE are very slow in this country in adopting reforms, for our reformers are often too extreme and it takes a long time to educate public opinion even half way. This is particularly the case as regards temperance, the thick-and-thin supporters of which may be divided into two classes—one believing in prohibition and determined to stop at nothing less, the other convinced that the proper method of reform is to place all sorts of restrictions on the public through the licensing laws. Both combatants pay little heed to the possibility of improving the liquor, which they are generally prepared to contend is bad at the best.

A correspondent—in the course of some remarks upon our article last week dealing with the alleged settlement of the question, What is whisky?—has brought to our notice some important facts concerning the control of the sale of potable spirits. The self-governing States of the British Empire have travelled a long way farther in real temperance reform than the Mother Country, and this time it is Australia that shows the way. The Customs and Excise regulations for spirits in the Commonwealth were much the same as in this country until a few months ago. The duties were somewhat higher and the margin between imported and home-made spirit a little wider, as befits a country prone to protectionist ideas, 14s. and 13s. per gallon respectively, against 11s. 4d. and 11s. Partly to increase the protection to the home distiller, about the wisdom of which there may be difference of opinion, and partly on moral and social grounds, about which there can be none, very considerable changes were effected last session. To begin with, the import duty was raised to 15s. per proof gallon. Then the Excise taxes were lowered to from 10s. to 18s., but it is in the graduation that the merit comes in. The lowest rate is applicable only to pure grape wine brandy and malt whisky, which will be admitted, according to predilection, as the best or least dangerous kinds of these forms of alcohol. We will quote intact the clause of the Act relating to whisky: "Whisky, distilled wholly from barley malt by a pot-still or similar process at a strength not exceeding 35 per cent. over proof, matured by storage in wood for a period of not less than two years, and certified by an officer to be pure malt whisky, per proof gallon 10s." The next rate in the

scale is for blended wine brandy which must contain not less than 25 per cent. pure grape wine spirit and pays 11s. Similarly blended whisky, distilled partly from barley malt and partly from grain, but containing not less than 25 per cent. pure barley malt spirit, pays 12s., as do also rum distilled from molasses and pure gin Spirits without ancestry or character are submitted to a tax of 13s. The graduation is not apparently very wide but it must be borne in mind that with the possible exception of high-class brandies there is no spirit that costs 3s. a gallon to manufacture in its natural state; consequently the worst spirit that has to pay 13s. costs more by the time it is cleared from bond than the best that has only to pay 10s. and thus the difference ought to be quite prohibitive as regards the former. We agree here, however, with our correspondent that "the system adopted by this Act is far from perfect." The best whisky, it is true, is distilled from barley malt; medium and passable stuff is obtained from maize and rice; and then there is a quick descent to potatoes, damaged grain, and even decayed and rotten fruit and vegetable matter. The last is supposed to be for methylation and industrial purposes, but there is no guarantee that some of it is not used for human consumption as a beverage. Besides, barley may be inferior or damaged, and the alcohol manufactured from it more mischievous than that obtained from sound grain of other descriptions, but so long as there is a margin of 2s. per gallon the chances are that the former will be used in preference, and the public be a loser rather than a gainer. The position is partially provided against by the time limit in the clause already quoted, which is really far more important than the graduated tax. Under the new Act no spirits are to be cleared for consumption unless they have matured in the wood for at least two years; and as regards importation, if spirits have not remained in bond during that length of time in Australia evidence must be afforded that they have complied with this condition elsewhere. Now good spirit improves with keeping and bad does not become good so there is a reasonable guarantee of good material if it has to run the gauntlet of at least a two years' novitiate.

But while the principle of this legislation is thoroughly sound, there are several reasons why its applicability is hardly the same in the United Kingdom as in Australia. One of these is the growing importance of alcohol in industry and the arts which renders it advisable to impose as few restrictions as possible on actual manufacture, whatever subsequent restraint may be placed on consumption. The real remedy in Great Britain is the time limit. If bad spirit will not mature so as to maintain any sort of fitness as a beverage it should be made so dear that no liquor dealer, wholesale or retail, could afford to sell it. This ought to be easily accomplished bearing in mind once more the low prime cost of most spirit. Let us take the existing duty as per basis, then instead of charging 11s. per gallon on all proof spirit, irrespectively of quality or age, let us suppose the charge to be made dependent on the spirit having remained in bond for four or even five years. If for every year short of that time there were added another shilling for duty, the clearance of inferior distilled spirit would in the ordinary commercial sense become prohibitive. The graduation indeed

by both Solon and Lycurgus; whilst Musonius, in a quotation preserved by Stobæus, says that the Greek legislators had forbidden women to practise such a thing and also to use any means for preventing conception. The "Apocalypse of St. Peter" discovered at Akhmîm in 1886 contains a scene in which the souls of unmarried women who have terminated their pregnancies by abortion are represented as being in hell together with the souls of the infants, and the latter direct jets of fire against their mothers. M. Reinach considers that this view of the criminality of abortion was derived from the Greek Orphic doctrines and that abortion was not reckoned immoral by the early Christians, but a very early extra-canonical Christian document known as the *Didachê*—i.e., "Teaching (of the Apostles)"—says: "Thou shalt not slay a child by abortion, nor what is conceived shalt thou destroy." Among nations or races who practised infanticide the prevention of childbirth does not appear to have flourished. There is one part of M. Reinach's argument which he develops elaborately but in which we are unable to agree with him. The description of the visit of Æneas to the underworld, which forms the principal subject of the sixth book of the *Æneid*, contains the lines (426-30):—

*Continuo auditas voces, vagitus et ingens
Infantumque animæ flentes in limine primo
Quos dolcis ritae exsortes et ab ubere raptos
Abstulit atra dies et funere mersit acerbo.
Hec juxta falso dantur crimine mortis.*

Before the gates the cries of babes new-born,
Whom Fate had from their tender mothers torn,
Assail his ears; then those whom form of lava
Condemned to die, when traitors judged their cause.

—Dryden.

In his metrical translation Dryden has expanded the phraseology of the original and introduced some ideas not expressly mentioned by Virgil. M. Reinach interprets the passage in a very different manner. He is so far from accepting the imagery of "tender mothers" that in his opinion the wailing infants had been the victims of abortion. Considering the singularly lucid and unaffected style of the *Æneid* (there are some riddles in the *Elogues*) the most easy and natural interpretation is that the infants had died while young without any specific reference to attendant circumstances. M. Reinach also seems to argue that because the French word "*sein*" means both "mammary gland" and "womb" therefore Virgil's "*ab ubere raptos*" may be taken to mean either "torn from the breast" or "torn from the womb." We cannot agree in this reasoning.

THE RESPECTIVE MERITS OF SEMMELWEISS AND OLIVER WENDELL HOLMES IN THE TREATMENT OF CHILD BED FEVER.

THE honour of priority in scientific discoveries is often claimed for more than one person and sometimes the balance of evidence is so even that posterity can never arrive at a unanimous verdict. The history of medicine supplies an instance of this kind in connexion with the prevention of puerperal fever—a disease which was once terribly rife in maternity hospitals but is now quite uncommon in hospital practice. In THE LANCET of August 4th, 1906, p. 301, we reviewed Dr. C. J. Collingworth's exposition of the part taken by Oliver Wendell Holmes, the American physician, in this great work, and afterwards, in our issue of Oct. 20th, p. 1090, we gave an account of the ceremonies at Budapest when the Hungarian memorial to Semmelweis was unveiled. In estimating the respective merits of these two great men the views of Dr. Collingworth and their natural complement in those of Professor T. Clifford Allbutt of Cambridge, who has said: "The Benefactor to whom the world's gratitude and memorial are due is he who makes the thing go, an achievement which comes after heroic sacrifice and a life's devotion, as in the instance of Semmelweis. That another man [O. W. Holmes] should have hit on the same idea, as some other

man always has, is to that other man's great *personal credit*, and he deserves the record in his biography, but if he did not expend himself upon it, and but for the man who did, the idea would have emerged and developed much later, I do not think he, but the effective person, deserves the chief honour."

THE DIRTY BLOTTING PAD.

It may reasonably be doubted whether the highly besmudged blotting pad is innocent as regards disease germs. In the act of writing the blotting pad is commonly breathed upon and bacteriological experiment has shown that micro-organisms may be projected a long distance by the breath. Blotting paper being an absorbent of moisture any septic matter would be rapidly dried on it and reduced to a readily transferable substance. Inkpots, again, are nearly always left open and consequently dust readily gains access to them, carrying in its load of micro-organisms. These in their turn are transferred by the pen to the paper and thence to the blotting pad, where they are left high and dry to be scattered once more in the room on the smallest provocation. Some inks, of course, contain an antiseptic but it is not likely that all inks serve as germicides. It may be a counsel of perfection to lay down that the blotting pad should be a fresh spotless sheet every day but when infectious respiratory disease is endemic such a precaution would not be so fatuous as might be supposed. Apart from this, everyone appreciates a clean blotting pad which will dry the writing without smearing it. Often enough the blotting pad is one mass of blotchy characters and ink-stains representing a usage of days, weeks, or even months. In such a condition its function has not only come to an end, any further use of it invariably leading to smears and annoyance, but it must be also bacteriologically filthy.

THE USE AND ABUSE OF SODIUM BICARBONATE.

In the whole range of drugs in common use there is perhaps none the pharmacological value of which is considered less open to question than sodium bicarbonate. It has enjoyed a wide vogue for many generations in cases of gastric pain and hyperacidity of the stomach. It is important, therefore, to notice in the *Bulletin des Sciences Pharmacologiques*, 1906, No. 10, a monograph by Dr. Léon Meunier in which the value of this classic remedy in allaying gastric pain is discredited. Dr. Meunier states that the action of the drug is generally explained in the following way. Gastric pain is due to an excess of hydrochloric acid, which causes no inconvenience during digestion owing to its absorption by the food. But when the stomach is empty the acid begins to exercise an irritating action upon the sensitive nerves of the mucous membrane. The acid is neutralised and as a result the pain is removed by the administration of bicarbonate of sodium at an interval of two, three, or four hours after a meal. Having doubts as to the validity of this theory Dr. Meunier set himself to investigate both clinically and chemically the part played by the drug. He found that in nearly every one of 16 cases the most severe pain was experienced when the hydrochloric acid in the stomach was at a minimum. As bicarbonate of sodium was uniformly successful in relieving the pain Dr. Meunier was led to attribute its beneficial action not to a mere neutralising effect but to the production of carbon dioxide which exerts a calmative effect on gastric pain. The acceptance of this hypothesis suggests the unsuitability of administering sodium bicarbonate alone as a source of carbon dioxide, since its therapeutic action is proportional to the quantity of hydrochloric acid present in the stomach and is liable, therefore, to great variations. Moreover, the saturation

parental control can be properly transferred to the decision of the licensing justices.

The whole question affords a fresh illustration, following many which have preceded it, of the inadequacy of present Parliamentary methods to meet the growing needs of a civilised community. In our elaborate social system new conditions which call for some adaptation to them of former laws, customs, or requirements are constantly arising; and we endeavour to meet these conditions by an adherence to methods of legislation which sufficed for the England of the STUARTS. Every Government department is aware of many directions in which law should be modified to meet the changing circumstances of the day; and every department alike shrinks from any endeavour to carry out what is seen to be necessary. There can be no doubt, of course, of the general wisdom of avoiding hasty legislation; but in this country we are fast falling into the very opposite error, and are permitting obsolete forms and superfluous precautions to stand in the way of changes which all admit to be required. The whole system of private Bills, of balloting, of blocking, and of many of the formalities of Parliament, is now far more operative in hindering useful measures of reform than in preventing changes for the worse; and it is high time that Parliamentary procedure was remodelled by the light of modern requirements. It ought to be rendered possible for the head of each of the great departments of the State to bring in a Bill containing any minor legislative changes shown to be necessary by the experience of the department over which he presides, to have these Bills examined and reported upon by a sufficiently large committee, and to have them pushed on to enactment by all the force of the Government. Mr. BURNS has lately told the House of Commons that the Local Government Board could not deal adequately with certain requirements about food until an amending Bill in relation to them had received the sanction of Parliament; and, as this amending Bill has perished along with others the public may still be poisoned with impunity. There are a score of questions as to which it is urgently necessary to increase the powers of the administration but as to which nothing is done, or probably will be done, until evils which might be nipped in the bud have become intolerable. And all this because the most crying administrative needs of the country are neglected or forgotten amid the bawling of politicians and of placemen.

Innotations.

"No quid nimis."

MALADVERTISEMENT.

ON more than one occasion under this heading we have commented upon the action of the Capsuloid Company in coupling the name of THE LANCET with the advertisement of their wares. In 1900 the Capsuloid Company sent to us specimens of hæmoglobin capsuloids. We analysed them at the time and stated in THE LANCET of August 11th, 1900, that they contained, as they then did, whatever they may do now, hæmoglobin in an oily excipient. The Capsuloid Company having obtained this testimonial, then flooded the press with advertisements setting forth the

virtues of capsuloids as promoting the growth of the hair. They added, "Send for Free Hair Booklet and copy of what 'The Lancet' says." We called their attention to this, and after some time they altered this statement into "See for Free Hair Booklet and copy of 'The Lancet's' statement." We have received many communications from various correspondents wishing to know if we in any way endorse the statement that capsuloids are good for the hair. We therefore wish to state distinctly that THE LANCET never said anything about hair or implied in any way that the hæmoglobin capsuloids had any influence upon its growth. The action of the Capsuloid Company in issuing these advertisements is distinct fraud upon the public. They imply, and deliberate so, that THE LANCET recommended capsuloids for the growth of the hair. This is not true, and the advertisement as it stands is written with the deliberate intention to deceive.

ARMY MEDICAL SERVICES: THE RECONSTITUTED ADVISORY BOARD.

IN our issue of Dec. 29th, 1906, we were able to lay before our readers an official communication from the War Office giving an account of the constitution of the reconstructed Advisory Board for Army Medical Services. The new Board was to consist of, in addition to the Director-General, a chairman, a civilian sanitary expert, a civilian physician, a civilian surgeon, and a civilian physiologist, an officer of the Royal Army Medical Corps specially qualified in sanitation, an officer of the Royal Army Medical Corps with special knowledge of tropical diseases, an officer of the Royal Engineers from the department of the director of fortifications and works, and the President of the Medical Board, India Office, as well as the Deputy Director-General, who will act as vice-chairman. Those representing the various positions above mentioned are as follows: chairman, the Director-General, Army Medical Service; vice-chairman, the Deputy Director-General, Army Medical Service; members, Colonel D. Bruce, C.B., F.R.S., M.B. Edin., R.A.M.C. (as expert in tropical diseases), Colonel G. K. Scott Moncrieff, O.I.E., R.E. (assistant director of fortifications and works), and Lieutenant-Colonel C. H. Melville, M.B. Edin., R.A.M.C. (as expert in sanitation). The civilian members are the following: Sir F. Treves, Bart., F.R.C.S. Eng., G.C.V.O., as civilian surgeon; Dr. J. Ross Bradford, F.R.S., F.R.C.P. Lond., as civilian physician; Dr. Louis C. Parkes, as civilian sanitary expert; Dr. M. S. Pembrey, as civilian physiologist; and Sir Charles A. Cameron, M.D. R.U.I., F.R.C.S. Irel., C.B., as representing Irish sanitation. The representative of the India Office is Surgeon-General A. M. Branfoot, C.I.E., I.M.S., retired; and the Secretary is Lieutenant-Colonel C. H. Melville.

ABORTION AMONG THE ANCIENTS.

THE declining birth-rate in France and many Anglo-Saxon countries has been much discussed recently chiefly from the modern ethical, sociological, and political points of view and not from the historical standpoint. An essay by M. Salomon Reinach, the eminent Parisian scholar, however, gives much information upon the subject of abortion in connexion with the morals and regulations of classical civilisation. He dwells upon the punishment stated by classic authors to have been inflicted in the Inferno in Hades upon women who had been guilty of the practice of abortion—a retribution, proved by various quotations, awarded to the criminals by the spirits of the children themselves in the Inferno. The evidence concerning the consideration by the ancients of abortion as a criminal act commences in Greece with the "Hippocratic oath" which says, "I will not give to any woman an abortive pessary." Galen tells us that abortion had been prohibited

yellowish discolouration of the sclerotics. The liver was smaller, the right hypochondrium was less full, and the hard consistence of the liver could be appreciated. The urine was slightly brownish and scarcely gave Gmelin's reaction. This case shows that epiploexy may produce in three years an extensive collateral circulation between the portal and systemic veins. M. Le Gendre and M. Deglos attribute the beneficial effect of the operation to the "blood-letting," which they think may have considerably modified the vascular condition of the liver and diminished the pressure in the biliary canaliculi. The diagnosis was hypertrophic cirrhosis of the liver.

HOSPITAL MISUSE AND EXCESSIVE MEDICAL CHARITY.

A MEETING of the Marylebone division of the Metropolitan Counties branch of the British Medical Association will be held at the rooms of the Medical Society of London, Chandos-street, Cavendish-square, at 8.30 P.M. on Thursday, Jan. 24th, when there will take place the second of a series of discussions on "Economic Problems in the Practice of Medicine." The motion submitted will be—

That the development of properly organised systems of mutual insurance for the costs of illness offers the most readily available method of reducing the admitted evils of excessive medical charity and the misuse of hospitals.

The debate will be opened by Dr. R. C. Baist, Mr. H. W. Armit, Mrs. Scharlieb, M.D., Dr. L. S. Moftmann, and Dr. J. H. Keay.

SPONTANEOUS ABORTION OF SYPHILIS IN THE PRIMARY STAGE.

It is generally accepted that in the absence of treatment the primary stage of syphilis is always followed by the secondary. At the American Association of Genito-Urinary Surgeons in New York last year Dr. R. W. Taylor of that city quoted Barnett's statement that in certain cases most typically Hunterian sores were not followed by secondary symptoms, and brought forward the following cases in support of this view. A Jewess, aged 14 years, had a typical indurated chancre of the lower lip, with a bubo of the size of a walnut. The secretion of the sore contained the *spirochæta pallida* in abundance. Mercurial plaster was applied but no constitutional treatment was adopted, as it was decided to await the development of systemic manifestations. The chancre subsided in about a month and then the bubo also underwent involution. Observation of the girl for eight months showed no constitutional symptoms. In a second case a woman was seen with an encrusted chancre on the right labium minus which had existed for two weeks. She had had coitus with only one man who was under treatment for an excoriated nodule in the coronal sulcus and inguinal buboes, and who subsequently developed constitutional syphilis. In the woman's case typical induration and pronounced adenopathy showed that she had received syphilitic infection. Under local antiseptic treatment she recovered in three months, to the surprise of Dr. Taylor. Her body was examined every week for six months, but no eruption could be found. She was watched for 18 months without further result. She married and had two healthy children. In a third case a man, aged 35 years, had a small chancreous erosion behind the sulcus and near the frenum which was regarded as suspicious and was treated with black wash. In three weeks the lesion developed characteristically. It presented marked induration and a greenish-yellow membrane. The efferent lymphatics and the vessels and glands became enlarged. Recovery followed. The patient was watched for five years without showing any evidence of constitutional syphilis. In a fourth case a man, aged 28

years, had a single coitus with a woman who was subsequently found to have condylomata of the vulva. Three weeks later he presented erosion and hardening of the lips of the meatus. Typical induration developed and extended half an inch backward with chancreous erosion and typical yellowish-green membrane. The inguinal glands became enlarged and hard. Under local treatment recovery took place. The patient was watched for 16 months and showed no signs of constitutional syphilis. Dr. Taylor referred to other reported cases, including one published by Kaposi. In all ten cases have been reported by seven observers. Probably many will require further evidence to convince themselves of the existence of exceptions to a well-recognised generalisation even when these are brought forward by such a well-known observer as Dr. Taylor. However, there is nothing unreasonable in supposing that certain persons may develop so great a natural resistance to the syphilitic virus that recovery takes place in the primary stage and the disease is aborted. Adopting the teaching of Sir A. E. Wright, we might suggest that inoculation of the virus is followed by the development of a high opsonic index.

NOTES UPON HEALTH RESORTS.

IN another column of this issue of THE LANCET a short article will be found upon the Riviera from the pen of Mr. James Stanley Little, and we take the opportunity of saying that we shall continue to publish at convenient intervals authoritative notes upon health resorts, continental and British. We have chosen a communication from a layman with which to start the series, because the layman puts his views in such a way that it can be at once appreciated what sort of information the public want from the medical profession. The questions asked of our readers by their patients concerning health resorts are not necessarily of a highly scientific character, but upon their answer may depend entirely the suitability of a particular locality for a particular case. All sorts of points of convenience and economy have to be considered in the recommendation of a place of sojourn as an adjunct to medical treatment, and it is a fact that the public is quicker to recognise this important point than its medical advisers have sometimes been.

AT the Medical Graduates' College and Polyclinic (Chenies-street, W.C.) to-day (Friday, Jan. 18th) a discussion on the Present State of the Leprosy Question in South Africa will be introduced by a paper read by Dr. R. Sinclair Black. Dr. Black was until recently the resident medical officer on Robben Island (the home for lepers of Cape Colony). His personal familiarity with the details of his subject may be expected to make the occasion one of unusual interest.

IN our reference last week to Sir Henry Pitman we stated that he was "but six months away from the hundredth anniversary of his birthday." We find that this is not quite correct, as he was born on July 1st, 1808, and consequently July 1st, 1907, would represent the commencement, not the conclusion, of his centenary.

Dr. H. Charlton Bastian will read a paper at the meeting of the Royal Medical and Chirurgical Society on Jan. 22nd, taking as his subject the *De-novo* Origin of Bacteria, Bacilli, Vibriones, Tornæ, and Moulds in certain previously Superheated Saline Solutions contained within hermetically-sealed Tubes.

A TELEGRAM from the Governor of the Mauritius received at the Colonial Office on Jan. 11th states that for the week

of the hydrochloric acid by the sodium salt retards the progress of gastric digestion, as pepsin acts only in an acid solution, and it further retards intestinal digestion, as the acidity of the gastric juice has been shown by Pawlow to be the specific excitant of the pancreatic gland. This drug may thus reduce a patient to a state of alkaline cachexia which led Trousseau to utter the dictum: "The abuse of alkaline drugs has done more harm than the abuse of mercury." Dr. Meunier suggests that it is more rational to produce carbon dioxide in the stomach by means of tartaric acid and a mixture of carbonates, so chosen as to evolve the gas slowly and continuously without modifying the acidity of the gastric juice. The tartaric acid is prescribed in one gramme powders and the alkaline powders contain sodium bicarbonate 0.4 gramme, calcium carbonate 0.3 gramme, and hydrated magnesium carbonate 0.2 gramme. The patient is directed to add an acid and an alkaline powder separately each to half a glassful of water and when the pain commences to take alternately tablespoonful doses of the acid and alkaline draughts. Dr. Meunier has found that gastric pain is most readily relieved by this treatment, whereas the administration of the alkaline draught alone is much less efficacious. From clinical experience he concludes that the carbon dioxide acts as a sedative by accelerating the evacuation of food from the stomach.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of the council of this Fund was held at the Mansion House on Jan. 10th, under the presidency of the Lord Mayor, for the purpose of filling vacancies on the council and committees. Among those present were Lord Oheylesmore, Sir Ernest Tritton, Sir William Selby Church, Sir E. Durning-Lawrence, Sir Savile Crossley, Mr. F. H. Norman, Mr. J. Astley Bloxam, Canon Fleming, Dr. J. G. Glover, Mr. T. Bryant, Mr. A. Pearce Gould, and Mr. Wakley. Mgr. Howlett, the administrator of the Roman Catholic Cathedral at Westminster, was elected to fill the place of Canon Pyke, who has resigned by reason of age, and it was decided to ask the Bishop of Southwark to make a nomination in the case of a second clerical vacancy. Lay vacancies were filled by the election of Dr. James Andrews, Mr. C. E. Layton, Mr. Frank Debenham, Mr. A. G. Phillips, and Mr. A. Millar, conditionally upon their willingness to serve. Sir Frederick Treves, Mr. Frank Bevan, and Sir Joseph Dimsdale were elected on the Distribution Committee, and a new committee, to be called the Finance Committee, was constituted as follows:—Sir E. Tritton, Sir W. S. Church, Sir John Bell, Mr. J. H. Hale, and Mr. J. H. Buxton. Lord Oheylesmore and Mr. Pearce Gould were elected to the General Purposes Committee.

"JUDY."

THE old-established comic paper *Judy* has been, we are informed, taken over by an entirely new management, and the proof of the change of spirit and tactics will be seen in the issue of the paper bearing to-day's date. It has been represented to us by Mr. F. W. Vogt, the new editor, that our leading article last week, commenting without regret upon the conviction of the late editor and proprietor Edward de Marny, might interfere with the success of what is practically a new and perfectly clean newspaper, and Mr. Vogt, at the same time, has forwarded to us an advance copy of the first issue under his superintendence that we may judge of the accuracy of his words. We congratulate him and his staff, and no less the new proprietor, upon the result of their revolutionary work. Every one of the offensive and mischievous advertisements of which we complained has disappeared, and *Judy* has become a perfectly respectable old lady, without, we may add, losing any of her power to amuse. We wish Mr. Vogt good luck in his intention to

regain for a widely-known and long-established newspaper the prestige of its earlier existence.

PRESENTATION TO MR. W. WATSON CHEYNE.

ON Dec. 21st, 1906, in the board room at King's College Hospital, Mr. W. Watson Cheyne was presented with his portrait by his old house surgeons and dressers as a permanent token of their esteem for his teaching and their regard for his scientific work. The presentation was made by Mr. Peyton Beale, as Mr. Cheyne's first house surgeon, on behalf of the subscribers. Dr. R. T. Hewlett moved a vote of thanks to the artist, Mr. W. O. Penn, for having produced such an excellent likeness, for it was greatly admired by all who had seen it. Mr. Cheyne expressed his thanks to the subscribers, saying that he should never forget how fortunate he had been in having such excellent workers in his wards.

THE EFFECTS OF EPILOPEXY FOR PORTAL OBSTRUCTION.

Talma's operation, or epiploxy, has been performed with considerable success for the treatment of the portal obstruction and consequent ascites due to cirrhosis of the liver. A collateral circulation is established between the portal system and the veins of the abdominal wall and the obstruction is relieved. Opportunities for observing during life the anatomical results of operation must be few. At the meeting of the Société Médicale des Hôpitaux de Paris on Nov. 30th, 1906, M. Le Gendre and M. Deglos reported the following case. A man, aged 39 years, was admitted into hospital on Feb. 18th, 1906. About six years previously he was addicted to alcohol and suffered from gastro-intestinal troubles. In 1903 he was in San Francisco and had jaundice but the feces remained coloured. Although he had no pains in the hepatic region gall-stones appeared to have been diagnosed and an operation was performed. Not finding any calculi the surgeon performed Talma's operation, although there did not appear to have been any signs of cirrhosis of the liver. The jaundice gradually diminished but six months later it recurred. In 1904 the patient returned to France where he was treated for 18 months without result by a number of practitioners. On admission there was deep jaundice, the urine contained an abundance of bile pigments, and there was obstinate constipation but the feces were of normal colour. The liver was enlarged, the spleen was palpable, and there was intense pruritus. The patient's condition became worse; incessant and more and more violent itching prevented sleep in spite of all hypnotics. He wasted and his colour changed from bronze green to olive green. The liver dulness measured 19 centimetres in the nipple line. The consistence and form of the liver were difficult to estimate as its lower border was masked by a broad and thick layer which extended to the right and left of the scar of the operation. The spleen extended below the ribs and measured 18 by 11 centimetres. There was slight pyrexia, the temperature rarely rising above 100.4° F. Laparotomy was performed in June, 1906; by M. Hartmann. On dividing the abdominal muscles no increased vascularisation of the subcutaneous tissues was found, but on dividing the muscles an abundant venous network which became almost angiomatous on reaching the external surface of the peritoneum was observed. The hæmorrhage was so severe that it was not thought wise to proceed and the wound was closed. After the operation the patient was in a state of profound depression which was thought to be hopeless. But a fortnight later some diminution in the jaundice was observed. He recovered and was able to leave the hospital with some jaundice and the liver and spleen nearly as large as before. In November, 1906, the jaundice had completely disappeared from the skin and there was only a slight

"The elements of the blood therefore visible by the microscope without any addition or manipulation are: 1st, the red corpuscles; 2nd, the colourless corpuscles; 3rd, molecules and granules in the interior of the colourless corpuscles; 4th, molecules and granules not inclosed in any corpuscular tunic; 5th, the fibrine." Under the action of reagents on white cells he describes the circulation of cell contents. Previously to Addison's time, white blood cells had been seen in the cold-blooded animals and were thought to be the nuclei of the red cells set free. Addison's experiments on inflammation and the vascular changes accompanied by diapedesis are quite as accurate as anything written within the last ten years.

It would follow as a self-evident conclusion that pus was altered colourless corpuscles, but with his usual correctness of detail he does not postulate this until he has carefully researched the component parts of pus. Here are his final deductions on pus: "The conclusions to which these experiments lead are, that pus corpuscles of all kinds are altered colourless blood corpuscles and that all liquid colourless, abnormal discharges are effusions of the liquor sanguinis, containing more or less of the fibrine and corpuscles in varying proportion. No new elementary particles are formed by inflammatory or diseased action." This is a wonderful advancement over the belief of his time—viz., that pus came from grown granules and molecules of the blood and tissues.

Addison's next field of research was the lungs and here again he is a pioneer, giving the first accurate description under the microscope of lung structure. It was necessary to know the normal to appreciate the abnormal deposits—viz., tubercles. The quotation of a few lines will enable one to grasp the clearness with which Addison worked out the minute anatomy of tubercle. "Objects composing tubercles of the lungs originate from blood corpuscles and not from any peculiar formation foreign to the normal structure of the tissues. In the first place a tubercle involves or includes in its substance the vesicular structure of the lungs; minute blood-vessels, lobular passages, and air cells, ... the blood-vessels are no longer permeable but their presence may be demonstrated. Secondly, I shall endeavour to show that the tubercles are composed of abnormal epithelial cells, ... Granulated corpuscles of a tubercle are sometimes very large (1/800 in 1/1000). There appears from my researches to be no distinction whatever between spots of lepra on the skin and tubercles in the lungs, if we except those arising from the different situation and function of the tissues."

William Addison's work was a stimulus to O. J. B. Williams, Wharton Jones, and James Paget, yet none of them seemed to have the accuracy and keen insight to recognise in the next 25 years that Addison's views of inflammation were essentially correct. In 1868, when Cohnheim first published his contribution on inflammation, the English pathologists began to discover that William Addison antedated Cohnheim's observations some 25 years. It has escaped observation, however, that he first recognised leucocytes as an integral part of human blood and that he attempted a classification of them on the bases of their granules, thus antedating Ehrlich's classification (1876) a third of a century. It is easily understood why his observations on leucocytes in inflammatory blood should have gone unnoticed inasmuch as it is only of recent date that it has become a subject of first importance to the clinician. The blood platelets, however, are a subject of interest to skilled investigation alone and it is difficult to understand how his observations remained unmentioned for 60 years.

* London Medical Gazette, December, 1840, and January, 1841.

DONATIONS AND BEQUESTS.—By the will of Mr. Arabella Vernon, of Penalt, Weston-super-Mare, Somerset, the following bequests are made: £2000 to the Royal National Hospital for Consumption at Ventnor; £2000 to the Royal United Hospital, Bath; £2000 to the Indigent Blind Visiting Society; £2000 to the Royal Hospital for Incurables, Putney Heath; £2000 to the West-End Hospital for Paralysis and Epilepsy, Welbeck-street; £2000 to the London Fever Hospital at Islington; £2000 to the Central London Ophthalmic Hospital; £2000 to the Central London Throat and Ear Hospital, Gray's Inn-road; £2000 to the Royal Hospital for Diseases of the Chest, City-road; £2000 to the Brompton Cancer Hospital; £2000 to the Deaf and Dumb Asylum (office in Cannon-street); £2000 to Guy's Hospital; and £2000 to the Rebuilding Fund of the Western Ophthalmic Hospital, Marylebone-road.

NOTES UPON HEALTH RESORTS.

A LAYMAN'S VIEW OF THE RIVIERA.

BY JAMES STANLEY LITTLE.

UNTIL comparatively recently the Riviera, in any case the French Riviera, had enjoyed an unassailed reputation as the health resort of the world. Even now, although that reputation has been challenged seriously from several quarters, the belief in its sanitary perfections is general and widespread. Without calling in question the substantial accuracy of this popular verdict, four seasons' residence from end to end of the Riviera, from Toulon to Leghorn that is to say, ought to bring home to any reflective person the fact that it is wise to recognise certain special or local conditions which go to qualify the unreserved acceptance of this enviable reputation.

It would ill become a layman to attempt to enter into those highly debatable and technical discussions as to whether the warm and sheltered parts of the earth are so favourable to consumptive patients as those altitudes to which many of our most distinguished chest physicians now send their patients. I may say in passing, however, that while I have personal knowledge of scores of consumptives who have been restored to health by the voyage to South Africa and residence in suitable parts of that benighted country, with equal opportunities of knowing I can remember comparatively few cases where the like happy result has followed on wintering in the Riviera. In any case it seems to be conceded, with something approaching unanimity, that persons hitherto free from pulmonary diseases run a risk, not inconsiderable, of contracting them in places where the air and soil are impregnated with the germs of lung disease. Latterly this consideration has operated in favour of the Italian Riviera, which, not being so full of tuberculous sufferers as the French Riviera, has been considered less dangerous as a health or pleasure resort. It has militated greatly against the popularity of such towns as Mentone. It seems to me that the clouds of dust which fill the air (a plague vastly increased in these days of automobilism), the startling variations in temperature experienced in any ordinary day from end to end of the Riviera, especially the chill dampness of the sunset hour, expose delicate persons visiting that coast to serious risks which they do not run in patronising many of the winter resorts of England. As touching this varying temperature, the changes in the weather in any one day, during the last four seasons in any case, have often been so great and so frequent that grave consequences have resulted to many invalids. Then there is that spell of three weeks' rain to be reckoned with, and those cyclonic storms, which are becoming so general as almost to change the character of the whole district so far as climate goes. This year the bad seasons of the previous three years has culminated, as all the world knows, in a ten days' storm of lightning, hail, and rain of unexampled severity. Indeed, it is necessary for the sick, and, for that matter, the sound also, to take great care and to adopt almost painful precautions in this country.

It is commonly asserted that the Italian Riviera, throughout its entire length, is damper than, and that the air lacks something of the stimulating and resilient qualities of, the French littoral. I should be inclined to dispute this view so far as the coast of the Alpes Maritimes is concerned. That coast, as a whole, does not compare favourably, I think, with many parts of the Italian Riviera from Ventemiglia to Spezia. Nor can it be said that in the matter of evil smells, the pollution of the foreshore and sea, and of the towns themselves, the French resorts are, on the whole, in any better case than their Italian rivals. The drainage of the former is generally of a more advanced type theoretically than that of the Italian towns. But the odours of Hyères, not merely those of the charming old town but of the fashionable quarters also, are as noxious as any one endures in the Italian towns and villages; while for general untidiness, and carelessness in disposing of household refuse, many centres of population in Provence, marine as well as inland, are as open to censure as the much abused cities and villages of Northern Italy. What saves Provence, or to be more explicit, what saves the littoral and its hinterland from Cannes to Hyères, and especially the nascent winter quarters between San Raphaël and Bormes, is the mistral, which blows away the smells and renders this stretch of the

ending Jan. 10th there were 15 cases of bubonic plague and 6 deaths from the disease.

Mr. Edward Mason Wrench, F.R.C.S. Eng., has been appointed a member of the Fourth Class of the Royal Victorian Order.

WILLIAM ADDISON, M.D.: THE WORLD'S FIRST HÆMATOLOGIST.

By HUGH A. MCCALLUM, M.D., M.R.C.P. LOND.,
ASSOCIATE PROFESSOR OF CLINICAL MEDICINE, WESTERN UNIVERSITY,
LONDON, ONTARIO, CANADA.

YEARS ago while waiting for the termination of a tedious confinement I was asked to inspect some medical books which the husband of my patient had obtained at an auction sale. Among them was Vol. XI. of the Transactions of the Provincial Medical and Surgical Association of 1842 (but published in 1843). It contained the plates and classical article on Inflammation by William Addison. This volume contains the presidential address by James Black. A glance at this retrospective address in medicine will give one a fairly accurate idea of the scientific attitude of the profession at that period on the subjects of blood corpuscles and inflammation. We find from this address that William Addison was then considered an authority on blood.

William Addison, who first discovered the meaning of diapedesis of leucocytes in inflammation, is little known by modern pathologists and clinicians. His name is usually confused with Dr. Thomas Addison, the discoverer of disease of the suprarenal gland, and at one time physician to Guy's Hospital, and for many years the acknowledged spirit which influenced the medical doings at this hospital. This is the statement of Sir Samuel Wilks, the biographer of Thomas Addison, and no higher tribute could be paid him, inasmuch as among his colleagues were such men as Bright, Hilton, Golding Bird, Hodgkin, Gull, Fagge, and Wilks himself. In addition to his celebrated monograph on suprarenal disease, which contains his classical description of progressive pernicious anemia, the life and labours of Thomas Addison are not only preserved by Guy's Hospital and its attached museum but by a biography of him written by Sir Samuel Wilks.

After searching the Library of the Royal College of Physicians of London one finds very little bearing on the life of William Addison. He practised at Malvern and was physician to H.R.H. the Duchess of Kent. His earliest writings were on the blood, published in the *London Medical Gazette* (December, 1840; January, 1841; March, 1841; and April, 1842). He delivered the Goulstonian lectures in 1859 on Fever and Inflammation (Dr. H. D. Rolleston kindly presented me with an autographed copy of a reprint from the *British Medical Journal* of these lectures). His works include three published volumes—viz., "Experimental Research with the Microscope," "Healthy and Diseased Structure," and "Cell Therapeutics." Like his namesake he wrote an extensive article on *Pneumonia*. I shall pass over all his other writings to point out some overlooked observations in his classical memoir "Blood Corpuscles, on Inflammation and on the Origin and Nature of Tubercle in the Lungs." This essay, with plates of microscopic structures, covers 74 pages, and some idea of the range of research can be gathered from the headings on its first page—viz., 1. Human Blood (a) red corpuscles; (b) colourless corpuscles; (c) molecules and granules; (d) fibrine. 2. Pus Cells. 3. Blood Cells and Lymph Globules of the Frog. 4. Inflammation. 5. Cells, flowers, fruit, leaf, pollen, grains, spores, animal; vesicle of the liver, epithelium, animalcules, colourless blood corpuscles. 6. Aeriferous Structure of the Lungs. 7. Tubercles. In speaking of his microscope, he remarks: "The powers I have used magnify 250 and 500 diameters linear." We see that he was equipped with dry lenses of fairly good powers. In addition to being the acknowledged discoverer of the part played by vessels and leucocytes in inflammation—antecedating Cohnheim 25 years—it can be fairly claimed for him that he was the world's first great hematologist. It was he in this same memoir who first recognised leucocytes as a separate blood element and the mammalia. Previously to his time and cell in man and the mammalia. Previously to his time and for years after leucocytes were recognised as the nuclei of the red cells: "A corpuscle deprived of its coloured capsule" the red cells: "A corpuscle deprived of this blood cell. In this

classical article on inflammation he gives a most accurate description and diagram of blood platelets. He was likewise the first to recognise the fibrillar arrangement of coagulation, and while he makes no statement his diagrams show he not only recognised its fibrillar arrangement but that these took origin from a mass of blood platelets. The use of reagents to determine the meaning of the granules in leucocytes he noted and described the circulation of contents in the leucocytes.

To enable one to obtain a clear conception of what William Addison is describing it will be necessary to consult his drawings among his five plates. In his discussion of human blood (on p. 237, paragraph 2) he says (in italics) "Two very distinct kinds of corpuscles may be distinguished in the blood." He directs to withdraw from the skin by puncture "a spot of recent blood," which is to be pressed into a thin film between two slips of glass. During examination he discovered corpuscles that had no disposition to adhere together in rows or irregular masses. After a very accurate description he says: "These are colourless corpuscles of the blood. By repeating the experiment with blood drawn from any inflamed surface as a pimple or the base of a boil, they are found to be abundant; and in the blood taken from the skin of a patient in scarlet fever or from the spots of any cutaneous disease they are remarkably numerous and conspicuous." Here the first hint in medical literature of leucocytosis (local general) in inflammatory conditions.

In Carpenter's "Human Physiology" (American edition 1858) one finds the following sentences (p. 222): "So, regards the human subject, Mr. Paget confirms (lectures on Inflammation in *Medical Gazette*, 1850, Vol. XLV, p. 97) the statement of Mr. Wharton Jones and Professor J. I. Bennett that the increased proportion of the colourless corpuscles which has been regarded by some observers (especially by W. Addison and Dr. C. J. B. Williams) as characteristic of inflammatory blood and particularly that which is drawn from an inflamed part is far from being a constant phenomenon." I merely quote you these words to show that he called forth in his own day, in a measure, confirmatory criticism.

To return to his knowledge of colourless corpuscles, he says: "They are seldom less in size than the red corpuscles frequently much larger. The central portion or inner vesicle (nucleus) is clearly defined, its outline appearing like a delicate filament just within the outer tunic of the corpuscle. The interval between the outline of the central portion and the outer circumference of the corpuscle is very small and without colour. Sometimes there is no interval between them and then the corpuscles have a uniform molecular aspect. The central portion has at all times a molecular or minutely granulated aspect and frequently one, two, or more granules during the observation become distinctly visible in it." Thus we have the first description in any tongue of mononuclear and polynuclear leucocytes. He then makes an attempt to determine the character of both red and white cell contents by use of "water, the dilute acetic acid, and liquor potassæ." In closing this paragraph of his paper he says: "These experiments lead to the conclusion that the colourless corpuscles are highly organised vesicles or cells circulating in, and forming a portion of, the blood."

On p. 241 of this volume we have paragraph 5 given over to a discussion on the "Molecules, Granules, and Fibrine." He says: "In the liquor sanguinis of buffy blood before it coagulates a great number of isolated molecules and granules, not enclosed in any corpuscular tunic, may be seen; they are mingled with the colourless corpuscles, but can never be confounded with them on account of their minute size. They are frequently seen in separate groups, which have sometimes a circular outline, appearing as if the corpuscular tunic had been dissolved away from around them. After a short time the fibrine may be seen coagulating." He then goes on to describe coagulation as seen under the microscope. In Plate 1, Figs. 7 and 8, he attempts to sketch what he is describing. A careful inspection of these figures along with the words of his text will convince anyone that he has seen and most accurately drawn the blood platelets and sketches fibrin formation as beginning in a group of them.

William Addison insists on the importance of the granules of a cell, saying: "It is the molecules and granules in its interior which give special qualities to the secretion or the contents of the cell." Half of Plate 3 and all of Plate 4 are given over to drawings of animal and vegetable cells to show the number and position of cell granules. He says:

proved that the death of a woman aged 53 years was due to heart failure from cystitis and chronic Bright's disease. The inquest was presumably held on account of the absence of a certificate of the cause of death, for it was shown that the deceased had asked a druggist to treat her and he had acceded to her request. The imprudence of this course was pointed out by the coroner, Mr. Frontbeck, who expressed a hope that the public by the publication of the details of such cases might be induced to refrain from putting pressure upon druggists to usurp the functions of the medical man. Fortunately for the druggist in the case mentioned the medical witnesses were able to say that the medicine given was such as might have been prescribed in the circumstances described, but he had arrived at it apparently through having suffered himself from similar symptoms to those which the deceased described to him and by remembering what his own medical adviser had ordered him to take.

THE REPORT OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

Sir Shirley F. Murphy's fourteenth annual report on the health of the administrative County of London in the year 1935 has just reached us. Like its predecessors the present volume is replete with information of interest and importance to dwellers in the metropolis, rich and poor alike. The report is divided into two sections. Part I, dealing with vital statistics and public health and Part II, being concerned chiefly with sanitary administration. In an appendix there appears the report of Dr. J. Kerr, the medical officer for education, which is dealt with elsewhere in our present issue, and the whole is prefaced, for presentation to the County Council, with an introduction by the chairman of the public health committee. This arrangement, whilst adding little to the value of the information contained in the report itself, is advantageous as a means of smoothing some departmental difficulties connected with the recent assumption of educational responsibilities by the central authority.

As usual, Sir Shirley Murphy's report opens with an analysis of the rates of marriages, births, and deaths, each of which attained its lowest point in the year 1935. With respect to the ages at marriage of Londoners, we note that as compared with previous years there has been in both sexes a decrease in the proportion of minors married to marriages at all ages. This feature, however, is observable not only in London statistics but also in those of the rest of England and Wales. The decline in the metropolitan birth-rate which has been manifest since 1871-80 has not been uniform throughout the administrative county. In all the registration districts of London save those of Whitechapel and St. George's-in-the-East there has been in recent years a decline of greater or less amount, but in these two districts the birth-rate has shown a not inconsiderable rise since 1881-63—a result, perhaps, indirectly due to alien immigration. From an interesting table in the text it appears that in most of the principal European towns there has been within the last 25 years a similar fall in the birth-rate, the decrease being most conspicuous in Brussels, Paris, Berlin, and Vienna, and least so in St. Petersburg.

As regards the relation of social condition to fertility of the female population Sir Shirley Murphy gives interesting information which is not generally accessible. In a useful table the rates are shown for groups of sanitary areas arranged with reference to the proportion of the inhabitants dwelling more than two in a room in tenements of less than five rooms. Very properly, the birth-rate has been calculated on the number of married women estimated to be living at child-bearing ages and not as heretofore on the total estimated population. On the other hand, for the reason that the previous places of residence of the mothers confined in such institutions could not be ascertained, no correction has been made for the very considerable number of births occurring in lying-in institutions. From this table we learn that the birth-rate is persistently higher in the more overcrowded and least affluent districts than elsewhere, the birth-rates varying from 2.03 per 100 married women, aged from 15 to 45 years, in Group I, where the overcrowding does not exceed 6 per cent. of the total houses, to 2.73 per 100 in Group V., where the overcrowding reaches 25 per cent.

In treating of the mortality of London in 1935, which he shows to have been the lowest on record, Sir Shirley Murphy reviews the ordinary methods of correcting death-rates for differences in the age and sex constitution of populations. These methods he illustrates by reference more particularly to two—the one generally known as the factorial method, the other, and more accurate, consisting in the application of the deaths at each age to a population of standard composition. It is the factorial method that has been adopted in this report because of its greater facility of application, as well as of the greater economy of arithmetical labour incidental thereto. But Sir Shirley Murphy is careful to note that by the method adopted he obtains results which, even in the case of the abnormally constricted population of Hampstead, do not differ from the methods of deaths in standard populations by more than about 1 per cent.—an error which in the circumstances may be regarded as negligible. The report contains a series of tables showing for the administrative county as a whole as well as for each of its sanitary areas the death-rate in proportion to estimated population, the figures being corrected by referring to the previous places of residence, the deaths occurring in public institutions. In order so far as practicable to eliminate error Sir Shirley Murphy has been at the trouble of constructing a life table for London on the basis of the census enumeration of 1931, thus ascertaining the expectation of life of Londoners at the several age periods dealt with in the tables. In another table the number of deaths in 1935 at each group of ages and for each sex is compared with the number that would have occurred had the rates in that year corresponded to the mean rates in 1891-1930. The number of lives gained in the year 1935 is also shown, the result being expressed in terms of "life capital," which result has been obtained by applying the mean future life term to the number of lives saved at each group of ages. The importance of presenting after this fashion the effect of sanitary administration in London will be appreciated when the fact is realised that in one year alone there has been a saving of 19,535 lives, representing a gain to the community of 757,016 years of "life-capital."

Prominent among social questions of first importance in the present day is that of the persistent decline in the fertility of our female population and its relation to the notoriously excessive loss of life that still prevails in early infancy. This question has recently been freely discussed in the public press, lay as well as medical, and the conference on infantile mortality held last autumn at the instance of Mr. John Burns has led to a further ventilation of the whole question which will, we trust, eventuate beneficially to the rising generation. In these circumstances we were prepared to find in the present report more than a passing reference to the subject of metropolitan infantile mortality. Availing himself of the returns made by medical officers of health to the Local Government Board on forms newly issued by the Board's medical department for the purpose of securing a more detailed account of infant mortality and its causes Sir Shirley Murphy has compiled an instructive table showing for the metropolis generally and for its several areas the deaths of infants from the principal causes in weeks and months of the first year of life. What is conspicuous in the sanitary history of the year 1935, as of other recent years, is the unfortunate fact that whilst the death-rate at all other ages shows a decrease from year to year the mortality of infants remains practically stationary. From the table last referred to it may be seen that of the deaths occurring within the first year of life nearly one-third take place within the first month and that in each successive month the number of deaths decreases until the ninth, when an increase is observed, due in all probability to the change of diet from natural to artificial. From a life table included in the text it will be gathered that the probability of an infant's living one month increases with each successive month until the ninth is reached when the probability is less than that in the eighth month of life. Whether or not this is a constant feature of infantile mortality in London can only be determined after more extended experience, for the figures now published relate to one year alone. But it is interesting in this connection that a similar life table published in the previous annual report, and based on the figures for the year 1932 presented by Dr. Tatham to the Inter-departmental Committee on Physical Deterioration, manifested a similar fall in the probability of living through the ninth month of life. That life table,

Riviera, in a far greater degree than any other part of the Mediterranean coast, bracing and invigorating. The fact remains, however, that here almost as much, if not quite as much, as in other parts of the French Riviera the number of victims to consumption among the natives reaches every year a very high percentage of the population. But this unhappy fact is due, I think, to morbid causes in which climate plays but a subsidiary part. It would take me too far afield to attempt to discuss this issue.

Again, it is not to be denied that this stretch of the Riviera is trying to the constitutions of persons whose maladies are purely nervous. On the other hand, despite what has been stated as touching the natives, it may be asserted, without fear of contradiction, that more remarkable cures of pulmonary disorders can be claimed by this coast than any other reach of the Riviera can establish. St. Maxime has a particularly happy reputation in this regard. I know, personally, of several well-authenticated cures effected in this little old-world village, which I have ventured to christen the "Margate of the Riviera." The famous Breton poet, Théodore Botrel, visits this tiny seaport—one of the few remaining untouched villages along the Riviera—every year. When he first made its acquaintance he was at the point of death.

If one may judge by certain habits of the people generally, no country the world over is more trying to the throat and vocal passages than the Riviera. Here, again, the short stretch of coast which lies off the P.L.M. from St. Raphaël to Hyères is favourably distinguished, since despite the fact that it is considerably colder than other sections of the littoral, its inhabitants do not habitually turn the earth into a spittoon in the manner of their near neighbours. Upon this habit, about its causes that is to say, certain Italian doctors, men of standing, have discoursed to me; but whatever the reasons, the fact remains that affections of the throat are extremely common both in Southern France and Northern Italy, in the interior as well as the coast. In Northern Italy nobody seems to possess a sound throat, and in many districts goitre is painfully prevalent. The inhabitants of the whole of this beautiful part of the world are not, it must be allowed, healthy in appearance, nor do they make, as a rule, old bones. But this perhaps is to be attributed mainly to the fact that they mature early in life, and that they pay scant attention to hygienic precepts in their manner of living.

To return to the visitors. There is another serious drawback to the Riviera which cannot be overlooked. Just as the inhabitants of any given town will aver vehemently that it is free from cold winds, evil smells, and other disagreeables, whilst its near neighbour is damned as the victim of all these ills; so as the visitor proceeds from end to end of the Riviera he is told in turn that the particular town he is instantly visiting is practically free from mosquitoes, though the towns to the right or left of it are eaten up by them. I find, as a matter of fact, that no exception is to be made: the whole coast is under the ban; though, of course, with differences. I have suffered cruelly, sleeping under nets too, in the best hotels of San Remo and Mentone for instance. The nets are some protection it is true, but woe betide the unhappy wight who becomes imprisoned with one or more of these pests as his sweet companion, for they creep in somehow. In any case nets are far from comfortable and they are not always forthcoming. The pastels—Zamparoni they are called from the name of their inventor—are also of limited utility. They send the robust insects to sleep for awhile and kill the weaker vessels. But it is not everyone can stand their fumes. They produce headache and are bad for the eyes and throat. I have smothered myself with mentholised vaseline, thymol powder, and a score or more odious specifics besides, but the wretched tormentors of one's slumbers are not to be denied. After a time their horrid little blast comes sounding over one's head and around one's ears. One feels like a man gagged and bound and covered by a fully charged revolver which he knows will be discharged at him sooner or later. I have been almost reduced to hysteria by their attentions and have spent a full hour night after night chasing the villains. Sleep is impossible and nervous prostration results. In estimating the pros and cons of wintering on the Riviera the miseries caused by these pestilential creatures, which sting you by night and by day, which are so hardy that this winter they have survived the ten days' cyclone of early November, must be taken into consideration.

Varazze, Italy.

MEDICINE AND THE LAW.

*The Golden Rules of Medical Evidence.*¹

A LITTLE work has recently appeared in the series of booklets called by their publishers the "Golden Rules Series," dealing with the giving of medical evidence and Dr. Stanley B. Atkinson, the author, lays down principles which are for the most part admirable. It is not always, however, easy to be brief and at the same time explanatory, and although the author, as a rule, makes his meaning clear we are not quite sure that we agree with his advice to a medical man anxious to escape attending as a witness if we have understood it rightly. He says: "If an appeal to the solicitor falls you may state that your memory of the events in question is vague, and when prompted you may find that the facts as known to you are quite hostile to his client's claim." If this is intended to cover all cases, including those in which the evidence, if given truly and frankly, would not be adverse, we should suggest modification; if, on the other hand, we have attached a meaning to the author's expressions which he did not desire to convey they might be made clearer. Nor are we convinced of the safety of a recommendation to be found on p. 21, with regard to the obtaining of a declaration from the lips of a person who may be dying as the result of an act capable of being charged as murder or manslaughter. Dr. Atkinson says: "Should death be imminent after a criminal assault (which includes abortion) the medical man should urge the victim to make such a dying declaration." It would involve the medical man in heavy responsibility should he have to repeat a declaration thus extracted in the witness box with the life of the prisoner in the dock dependent upon its absolute accuracy. The dying person conscious of impending death may be assumed by the law to speak the truth but no such assumption renders him infallible and in conceivable circumstances he may have been under a mistaken impression which a living witness would be able to correct. It is one thing to receive such a declaration or even to encourage the utterance of that which may be useful in the cause of justice; to "urge" it is a very different matter. The pages devoted to informing and reminding the medical man of points relating to the preparation and giving of his evidence where it is strictly of a medical character are, however, of a useful and practical nature and we note that matters of detail hardly to be described as rules of medical evidence have not been too rigidly excluded—e.g., a reminder that "it is dangerous to attend lying-in women after making an autopsy." It is more easy, however, to lay down apparently simple maxims than it is to obey them. We find, for example, on p. 31 the golden rule, "Say exactly what you mean," which all honest men endeavour to do but which sometimes through their very desire to be accurate they fail to achieve with complete success. "Avoid appearing suspicious" is another maxim on the same page, which suggests as a possible preliminary warning, equally needed, "avoid being suspicious," although neither would always be easy to obey. Occasionally a "golden rule" may require amplification in order that it may be clearer, but we can point to one propounded by Dr. Atkinson which would be as easily understood, and no less generally applicable, if two words were elided: "Little is gained by cross-examining one who is obviously telling the plain truth." The words which we have put in italics are surely superfluous, particularly to those who are willing to understand that the "truth" implies the truth of the witness's oath—i.e., "the truth, the whole truth, and nothing but the truth." Most counsel will agree that the witness, whether he be a skilled witness of fact or one called as an expert who is master of his facts and narrates them simply, concealing nothing, is not likely to be seriously "knocked about" by the most skilful cross-examiner "within" or "without the bar." Still less is he likely to suffer either apparently or in reality if he has been called by an advocate with the knowledge necessary to re-examine properly and to correct any false impression liable to be founded upon the cross-examination.

Prescribing by a Druggist.

In the course of a recent inquest at Westminster it was

¹ Golden Rules of Medical Evidence, by Stanley B. Atkinson, M.B., B.Sc., of the Inner Temple, Barrister at Law. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1906. Pp. 63. Price 1s.

The rates in the eight Scotch towns ranged from 18.2 and 19.2 in Paisley and Edinburgh, to 24.0 in Perth and 25.6 in Greenock. The 721 deaths in the eight towns showed a decline of 75 from the number returned in the previous week, and included 67 which were referred to the principal epidemic diseases, against 55 and 71 in the two preceding weeks. These 76 deaths were equal to an annual rate of 1.9 per 1000, which exceeded by 0.5 the rate from the same diseases in the 78 English towns; they included 19 which were referred to whooping-cough, 18 to "fever," 12 to diarrhoea, nine to measles, six to diphtheria, three to scarlet fever, and not one to small-pox. The 19 fatal cases of whooping-cough showed a slight increase, and included 13 in Glasgow and four in Greenock. The 18 deaths from "fever" exceeded the number in any recent week, 14 occurring in Glasgow and four in Edinburgh; 11 of these "fever" deaths in Glasgow and three in Edinburgh were certified as cerebro-spinal meningitis. Four deaths were attributed to diarrhoea both in Glasgow and in Edinburgh. Five fatal cases of measles were returned in Aberdeen and two in Edinburgh; three deaths from diphtheria and the two from scarlet fever were recorded in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 119, 167, and 182 in the three preceding weeks, further rose to 185 in the week under notice, and exceeded the number returned in the corresponding week of last year by 59. The causes of 22, or 3.0 per cent., of the deaths registered during the week in the eight towns were not certified or were not stated; the mean proportion of uncertified deaths in the 76 English towns during the week did not exceed 1.0 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 28.8, 18.4, and 31.9 in the three preceding weeks, declined again to 29.0 in the week ending Jan. 12th. During the 13 weeks of last quarter the death-rate in the city averaged 23.9 per 1000, the mean rate during the same period being only 16.0 in London and 16.2 in Edinburgh. The 219 deaths of Dublin residents during the week under notice showed a decline of 22 from the high number in the previous week, which excess was mainly due to the delay of registration during the Christmas week; they included eight which were referred to the principal epidemic diseases, against five and 19 in the two preceding weeks. These eight deaths were equal to an annual rate of 1.1 per 1000, against 1.2 in London and 1.8 in Edinburgh. These eight deaths from these epidemic diseases in Dublin last week included three from measles, two from whooping-cough, two from diarrhoea, one from "fever," and not one either from scarlet fever, diphtheria, or small-pox. The fatal cases of measles corresponded with the number in the previous week, while those both of whooping-cough and diarrhoea showed a marked decline. Four inquest cases and one death from violence were registered during the week; and 87, or 40.1 per cent., of the deaths occurred in public institutions. The causes of seven, or 3.2 per cent., of the deaths registered in the city during the week were not certified; the percentage of uncertified deaths in the week under notice did not exceed 0.2 in London, while it was 3.1 in Edinburgh.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Fleet Surgeons: P. V. Jackson to the *Sapphire* on recommissioning, and P. E. Melchard to the *Majestic*. Staff Surgeon: J. Martin to the *President*, for three months' course at West London Hospital. Surgeon: F. O. Robinson to the *Sapphire* on recommissioning, to be lent to the *Tyne*.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1891, Staff Surgeon Albert Robart has been allowed to withdraw from His Majesty's Naval Service with a gratuity.

ROYAL ARMY MEDICAL CORPS.

Major R. W. H. Jackson, specialist sanitary officer at

Dublin, is appointed to the Belfast District. Captain E. Brodribb, from Gibraltar, is appointed for duty at Kilkenny, and Captain S. de C. O'Grady from Limerick to Dublin. Captain F. S. Penny joins the London District for duty.

ROYAL ARMY MEDICAL CORPS IN INDIA.

Lieutenant-Colonel J. J. O. Bennett has assumed command of the Station Hospital, Saugor, on return from leave. Major F. W. Begbie has been posted for duty in the 5th Division. Captain L. L. G. Thorpe has returned from leave and has arrived at Jubbulpore. Captain A. W. Gibson has left Dthala for Aden. Captain T. F. Ritchie is granted 60 days general leave from Dec. 7th, 1906. Lieutenant J. Campbell is appointed specialist in the prevention of disease.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Major-General Lord Oheylesmore, O.V.O., will distribute the prizes of the London Companies Royal Army Medical Corps (Volunteers), on Saturday, Feb. 9th, at their headquarters, 51, Calthorpe-street, Gray's Inn-road, London, W.C.

MR. HALDANE'S NEW ARMY SCHEME.

The Army Order recently issued puts us in possession of some very important information regarding the great changes, which are still, however, quite incomplete, proposed to be carried out in Mr. Haldane's new army scheme. There is little or nothing in the Army Order or in the explanatory memorandum accompanying it which calls in any special way for medical comment. Nevertheless, as no great and fundamental changes can take place in the army as a whole without more or less affecting every branch and department of it, and as the present War Minister's declared aim and object are to develop, if not to create, a national army and to organise a new and comprehensive system of national defence we may venture to express some of the impressions that have occurred to us. Seeing, moreover, that any movement in this direction is necessarily intimately associated with that of the maintenance of our national stamina and vigour it becomes a question of public health. On this relation, however, there is no need to enter here beyond calling attention to the important bearing which it has upon this army problem. As regards the titular changes introduced, for British military purposes a division is a handier tactical unit and one more in accordance with the army traditions of this country and with the present organisation of our Indian army than an army corps. Divisions and brigades lend themselves well to army medical organisation purposes. We can only suppose, however, that before Mr. Haldane for economical reasons made the reductions that he did in the regular army of trained soldiers he had taken some steps to ascertain how his new proposals for recruiting and reorganising the regular army from the non-regular—as to foreign service, for example—were likely to be received and to work, for on this success mainly depends. It is as impossible to have a river without water as an army without recruits, and the quality, in training and efficiency, of any force to take the field against that of a Continental Power has in the present day to be of the best. As we have already said, no one can doubt Mr. Haldane's sincerity of purpose and breadth of view. The object which he seeks has, and should have, no element of political party spirit about it. The appearance of his complete scheme will naturally be awaited with great interest and curiosity, and should it prove reasonably adequate to the needs of the occasion and likely to lead to some settlement of this question on a satisfactory basis he will have well deserved all the praise which he will surely obtain from men of all parties.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on Jan. 15th, when Sir J. Dick, K.C.B., presided, the sum of £62 was distributed among the several applicants.

THE NEW ARMY MEDICAL SERVICE ADVISORY BOARD.

The personnel of the reconstructed Advisory Board formed by the amalgamation of the Army Medical Advisory Board and the Army Hospital Sanitary Committee has now been announced. We publish the names in another column (see p. 178) and believe that our readers will agree with us that the selection of members has been made judiciously.

however, showed a fall in the probability in the seventh month of life which is not noticeable in the table for 1905.

The influence of social condition on mortality at different periods of the first year of life is well shown in a table in which are compared the rates of infant mortality obtaining in groups of metropolitan districts arranged according to degrees of overcrowding as revealed by the recent census. Allowing for some irregularities in the rates due to the fact previously noted that the births in lying-in institutions have not been distributed to the districts in which the mothers reside, it appears that the mortality of infants in their first year increases with the proportion of the population at all ages living in overcrowded tenements. When the figures for each "trimester" are considered the same phenomenon is observable but the fact particularly deserves notice that the difference in mortality between the least and the most overcrowded groups is the least marked in the first three months of life, more marked in the second, still more marked in the third, and most marked of all in the fourth three-month period of life. This important question of the influence of social condition on infantile mortality is brought into prominence for the first time in the present report. Unfortunately a similar method has not as yet been attempted for other parts of the United Kingdom, but until this has been done no trustworthy data will be available whereby the relation of social circumstances to infant vitality can be looked for. Sir Shirley Murphy has divided the districts of London into five groups in the increasing order of overcrowding, the first group showing a proportion of 8 per cent. of the population living in one room and the fifth group a proportion of 28 per cent. Owing probably to the more complete registration of births and deaths in the better circumstanced districts the mortality in the most overcrowded group in the first month of life scarcely exceeds that of the group that is least overcrowded. As age progresses, however, the difference increases and this may be due either to decrease of the difference of death registration in the several districts or to "the effect of environment becoming more marked as it is afforded a longer time in which to operate." Although Sir Shirley Murphy very properly hesitates to strain inferences from the experience of a single year, nevertheless he thinks that the figures which he has published tend to invalidate the conclusion expressed by some persons that ante-natal conditions constitute a predominant factor in determining infant mortality.

Looking Back.

FROM

THE LANCET, SATURDAY, Jan. 17th, 1829.

REMARKABLE CASE OF COMPLETE ABSTINENCE.

ANNA GARBERO, of Racconis in Piemont, died on the 19th of May, 1828, after having been for two years, eight months, and eleven days, without any solid or liquid nourishment. Sixteen hours after death she was examined by MM. Rolando and Gallo, of Turin. The serous and synovial membranes were dry, and resembled parchment; the diameter of the principal veins and arteries was much less than usual, but the most remarkable morbid alteration was that of the digestive organs; the transverse colon had descended to the hypogastric region, its two extremities remaining fixed in their natural situation; the stomach had descended in a similar manner; and being much contracted, had the appearance of part of the larger intestine. The duodenum was in a natural condition, but the other small intestines were considerably contracted; the lower part of the cæcum, and the middle portion of the transverse colon, contained small hardened scybala; at the lower part of the colon descendens, the membranes of the intestinal canal were thickened and callous, so as to hinder the further progress of the excrement; and in the sigmoid flexure, it was completely obliterated. The mucous membrane of the stomach was softened and friable; that of the intestinal canal had undergone the same alteration, and was of a brown colour, such as is observed in incipient gangrene; the valvæ conniventes were hardened, and the whole tract of the small intestines was empty. The mucous membrane of

the rectum was of a violet colour, thickened, beset with hard scirrhous excrecences, and covered with very foetid pus. The mesenteric glands were in a natural condition; the epiploon and mesentery exhibited no traces of fat, and were nearly in the same state as the pleura and peritonæum.—*Annali di Omodei.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9413 births and 6348 deaths were registered during the week ending Jan. 12th. The annual rate of mortality, which had been equal to 19·7 and 22·4 per 1000 in the two preceding weeks, declined again to 20·7 in the week under notice. During the 13 weeks of last quarter the death-rate in these towns averaged only 16·2 per 1000, the rate during the same period in London being 16·0. The lowest death-rates in the 76 towns during last week were 8·7 in Hornsey, 10·3 in King's Norton, 14·3 in Willesden, and 14·4 in Aston Manor, in Rhondda, and in Barrow-in-Furness; the rates in the other towns ranged upwards to 30·2 in West Bromwich, 31·5 in Brighton, 31·8 in Hanley, and 32·8 in Middlesbrough. The 6348 deaths in the 76 towns showed a decline of 531 from the high number in the previous weeks, which was partly due to the delay of registration during the Christmas holidays. They included 423 which were referred to the principal epidemic diseases, against 430 and 478 in the two preceding weeks; of these, 140 resulted from measles, 91 from whooping-cough, 70 from diphtheria, 47 from diarrhoea, 41 from scarlet fever, 34 from "fever" (principally enteric), and not one from small-pox. The deaths from these epidemic diseases were equal to an annual rate of 1·4 per 1000 in the 76 towns; the rate in London from the same diseases did not exceed 1·2. No death from any of these epidemic diseases was registered last week in Halifax, Northampton, York, Coventry, or in eight other of the 76 towns; the annual death-rate therefrom, however, ranged upwards to 4·7 in Smethwick, Bootle, and Hull, and 8·2 in Warrington. The fatal cases of measles showed the largest proportional excess in West Ham, Leicester, Bootle, Rotherham, Hull, and Warrington; and whooping-cough in Huddersfield, Leyton, Rotherham, and Walthamstow. The 70 deaths from diphtheria showed a decline of 29 from the number in the previous week, but this disease caused a high death-rate in Reading, Smethwick, and Leyton; the deaths from scarlet fever also showed an excess in Smethwick and Hanley. The deaths referred to "fever" included 11 in London, two in Birmingham, two in Salford, two in Blackburn, and two in Swansea. The fatal cases of diarrhoea were fewer than in recent weeks. No case of small-pox has been under treatment in the Metropolitan Asylums Hospitals since the end of June last. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 3846 and 3707 in the two preceding weeks, had further declined to 3521 at the end of the week under notice; 285 new cases were admitted to these hospitals during the week, against 237 and 309 in the two previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had steadily increased in the six preceding weeks from 312 to 718, declined again to 620 in the week under notice, but exceeded the corrected average in the corresponding week of the last five years by 261; 83 deaths were also referred to influenza. The causes of 62, or 1·0 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Salford, Newcastle-on-Tyne, and in 38 other of the 76 towns; the proportion of uncertified deaths, however, again showed a considerable excess in Liverpool, Birmingham, St. Helens, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19·0 and 22·9 in the two preceding weeks, declined again to 20·8 in the week ending Jan. 12th, and was almost identical with the rate recorded during the same week in the 76 English towns.

CYANOSIS AND INDISCRIMINATE SELF-DRUGGING.

To the Editors of THE LANCET.

SIRS,—I have read with pleasure and also with no little benefit the interesting lecture by Dr. Thomas Oliver which appeared in THE LANCET, Dec. 29th, 1906, p. 1772, which warningly illustrates the ill-effects upon the body which may be brought about by the indiscriminate self-drugging with medicaments ordinarily regarded by the public as non-injurious even if non-effective. It is scarcely to be expected that the lay person should know whether or not certain drugs are or are not more than ordinarily injurious; as a matter of fact, he or she commonly regards them as being safe principally on account of the ease with which they can be procured and the publicity given to the class of medicine by its exposure in the windows and show cases of chemists' shops, contained, as it usually is, in the pleasing and portable little tin-stoppered bottle.

The lecture recalls to my mind two cases which have occurred in my own practice during the last 12 months, in both instances in women, and I should perhaps not have noted the effect of this class of drug had it not been that the symptoms of the second case were practically identical with those of the first. The first case was that of a nurse, aged 30 years, who for some time had suffered from dysmenorrhoea, but which latterly had been of such severity as to cause her to resort to drugging; on the night the incident occurred she had taken two antihemorrhagic pellets but as she got no relief from them within an hour she took two more. In about an hour's time she was seized with violent pains in the lower part of the abdomen, accompanied by an urgent condition of dyspnoea with pallid face, blue lips, ears, nose, and finger tips; the pulse and respiration-rates were both increased in frequency. She said she had at the time a feeling of impending death. She was given a little brandy and water and when I saw her I ordered fomentations to the lower abdomen. She was apparently quite well again in an hour and a half.

The second case, also a nurse, aged 27 years, although robust looking, had suffered six years previously from scarlet fever complicated by pleurisy and albuminuria; she was never free from a slight albuminuria and had recently been troubled with nasty headaches on and off. She was given four antipyrine pellets by another nurse who was in the habit of taking them for headache. She took all four at once and about half an hour later she was taken ill and with the exception of the absence of abdominal pain she had similar symptoms to the previous case, but had a more marked and prolonged initial faint. She was put to bed and was given a little brandy and water with hot applications over the precordial region, and was apparently quite well again in about three hours.

I am, Sirs, yours faithfully,

JOSEPH BEARD, F.R.C.S. Edin., D.P.H. Camb.

Bottle, Jan. 2th, 1907.

THE CASE OF GEORGE EDALJI: A QUESTION FOR OPHTHALMOLOGISTS.

To the Editors of THE LANCET.

SIRS,—Might I ask you in the cause of justice to permit me to put the following question to those of your readers who are engaged in eye practice:—

"Do you consider it physically possible for Mr. George Edalji, whose degree of myopic astigmatism as determined by retinoscopy under homotropine is

Right eye — 8.75 diag. sph.
— 1.75 diag. cylind. axis 90°.
Left eye — 8.25 diag. sph.

to have set forth upon a pitch dark night with neither moon nor stars, to have crossed country for half a mile climbing fences, falling gaps in hedges, and passing over a broad railway line, to have found and mutilated a pony which was loose in a large field, to have returned half a mile, and to have accomplished it all under 35 minutes, the limit of the possible time at his disposal? Mr. Edalji did not wear spectacles."

A consensus of scientific opinion upon this point would greatly aid me in setting justice for this young professional

man, condemned for an offence which in my opinion he could not possibly have committed.

I am, Sirs, yours faithfully,

ARTHUR CONAN DOYLE, M.D.

Underham, Hindhead, Surrey, Jan. 15th, 1907.

AMYL NITRITE IN HÆMOPTYSIS.

To the Editors of THE LANCET.

SIRS,—If I have read him correctly, Dr. Albert Abrams in his two recent letters on the above subject maintains that amyl nitrite inhalation promotes hæmostasis of the lung largely through reflex action. The vapour of the drug stimulates the terminations of the vagus in the nasal mucosa. Thence reflexly the longitudinal muscular fibres of the bronchioles are made to contract and express the blood from the lung parenchyma. This seems overmuch to expect from the "weaker longitudinal fibres." But whether or no these be competent for the task, it is certain that amyl nitrite can render the lung more or less exsanguine without assistance from the nasal mucosa or its nerve supply. In the laboratory demonstrations by Pic and Petitjean, the lung was rendered so anemic that when incised no single drop of blood escaped. Yet the amyl nitrite responsible for the result was injected into the femoral vein. Further, nitroglycerine given by the mouth has proved no mean substitute for amyl nitrite inhalation in some cases of hæmoptysis.

Referring to the inhibitory influence of amyl nitrite on uterine hæmorrhage, Dr. Abrams expresses the opinion that the drug "acts on the fibres of the uterus with secondary constriction of the blood-vessels." An action on the uterine musculature, so far as I know, has not been hitherto postulated of the drug. But even if true, how could such action explain the influence of amyl nitrite on the hæmorrhage which follows removal of parovarian cysts and on that which accompanies rupture of the sac in ectopic gestation?

In point of fact, the only physiological action of amyl nitrite which rests on any secure foundation is the sudden production of vaso-dilation—or, in other words, the sudden inhibition of vascular tone—in wide areas, if not generally; this being of necessity associated with a fall of blood pressure and a compensatory acceleration of the heart beat. All other actions ascribed to the drug would appear to depend on mere inference from preconceived theories. For example, from the relief sometimes afforded by it in the asthmatic paroxysm, amyl nitrite is inferred to have the power of relaxing the bronchial muscles. But the inference is unjustifiable because the view that asthma depends on bronchial constriction remains an unverified hypothesis. The only view of the mechanism of the asthmatic paroxysm which is consistent with the known physiological action of amyl nitrite, is the vaso-motor hypothesis: amyl nitrite relieves asthma by relaxing the peripheral vaso-constriction which is an essential factor in the bronchial vascular distension responsible for the obstruction to respiration.

I am, Sirs, yours faithfully,

Upper Norwood, Jan. 12th, 1907.

FRANCIS HARE.

GAS FIRES.

To the Editors of THE LANCET.

SIRS,—We have read with interest Mr. Francis Jones's letter in THE LANCET of Dec. 15th last criticising the results of the recent inquiry held by the Coal Smoke Abatement Society on gas stoves and should be glad if you can find space for the following reply.

Length of the tests.—While admitting that, within limits, a long test is preferable to a short one, we consider that in practice a full working day is quite sufficient. In this conclusion we are supported by the accepted practice in the case of boiler trials. The purpose of the inquiry being to provide data upon which to base general conclusions as to gas stoves, an investigation into the behaviour of 25 different stoves in different rooms is surely far preferable to a test of only one stove in one room, however long continued, which was, we believe, the condition holding in Mr. Jones's experiments. We consider it quite impossible to arrive at sound general conclusions as to the value of gas-stoves from such a test, however instructive the results may be in other ways. A peculiarity in the room or stove may vitiate the entire results.

"Audi altorum partem."

SECURITY OF TENURE FOR POOR-LAW MEDICAL OFFICERS IN THE HIGHLANDS OF SCOTLAND.

To the Editors of THE LANCET.

SIRS,—Security of tenure for Poor-law medical officers in Scotland is so well recognised as right and proper that without any special enactment it has gradually but surely become the rule except in the remoter parishes of the Highlands and Islands. No doubt the law of the land should in explicit terms reinforce the practice. But security of tenure cannot be made legally absolute "*ad vitam aut culpam*." It can only be relative—that is, there must be the power of dismissal still left with the parish authorities but subject to the intervention of the Scottish Local Government Board. This Board has to be made the judge as to whether the dismissal be capricious and unjust or not.

Had the Local Government Board 40 years ago laid down that the power of dismissal was only to be exercised subject to its approval as one of the regulations in connexion with the Parliamentary grants in aid of Poor-law medical relief, I have no doubt such a restriction would then have been quietly accepted as a necessary condition of help from the State. But, Sirs, the times change and we have to change with them. Two things have happened. Gradually parochial boards have come to see that their officers deserve, and should possess, security of tenure. And so it may truly be said that parochial medical officers all over Scotland with the exceptions I have mentioned do already hold their appointments "*ad vitam aut culpam*." The other change which also I can say on looking back nearly 50 years, a great part of which was passed as a parish doctor, has come about, is that Scottish feeling as against central interference of all kinds has waxed very much stronger, and, rightly or wrongly, parish councils in the larger centres will not allow that the Local Government Board should have any legal right whatever to interfere with their jurisdiction. And so the chances of a change in the law, however reasonable, yet as tending, however remotely, towards centralisation are to those studying the trend of the times absolutely nil and the agitation in that direction useless. If this contention be right, surely, Sirs, it is wiser to limit our attention to the diseased portion of the existing system and leave the healthy part alone.

Pain and disturbance of function are practically—nay, I may say invariably—limited to the extremities of the Scottish body politic, the Highlands and Islands. What, then, is the cure for this complaint—a complaint, unfortunately, too frequent and one which no unprejudiced person can deny really exists and demands remedy. Owing to the widely scattered and poor condition of the inhabitants in those remote regions it has become necessary to pay the parish doctor at a much higher rate per head of paupers than the ordinary parochial medical officer is paid in the more densely populated and richer parts of the country. Again, from the very nature of things, the Highland and Island doctor is appointed, not only to look after the paupers, but also he has to attend those of the parish inhabitants, be they rich or poor, who may require his services. In this way he becomes a sort of club doctor and the invariable evils of contract practice immediately begin to grow and flourish. His employers, partly by salary from their own pockets, partly by securing larger and larger grants from the public purse, claim that they have the right, not only to his services, but to dictate on private and personal grounds that they themselves should be judges of the skill and attention he should bring to bear on the discharge of his professional duties. Surely, Sirs, a ridiculous state of things if the doctor is to be in any sense independent, and if he is to exercise that indispensable qualification for real usefulness in his work. No doubt legal security of tenure would help him. But to those who know the real nature of the working of the existing state of things much more than security of tenure is required if the condition of the Poor-law doctor in the Highlands and Islands is to be placed on a satisfactory footing. Even with security of tenure he would still be

ill-paid, ill-housed, a prisoner practically in his parish, and unpensioned for his old age. The state of matters of which we have read so much as existing in Ireland is practically going on on this side of the Irish Sea in a great portion of the north and west of Scotland.

Is the real remedy here, as there, to be a State-paid medical service? From the purely professional point of view there is much to be said in favour of this proposal, as there is in the corresponding case of education. The position of a civil servant is assured, his salary and pension are fixed and certain, and, above all, merit would be more likely to be recognised and promotion to follow would almost come to be relied on.

But with all due deference to Mrs. Sydney Webb, I do not think the country is prepared for such a 'grave socialistic and centralising experiment.' No doubt, as that great authority on local government shows, we have travelled far on the same road in the matter of public health in supplying free of charge to rich and poor infectious diseases asylums and are fast giving to all and sundry gratuitous medical advice and medicines in our general hospitals. But, looking forward, as we are entitled to look, hopefully to great advances in sanitation, housing, proper upbringing of children, physical training of the pupils, and medical inspection of schools, is there not a real prospect of abolishing what may be called the policy of mere expedients to meet present difficulties? It may be visionary, but having secured the reforms mentioned there is really no reason why each individual should not sit down under his own vine and fig tree, when he will have learned not only to avoid all known causes of infection but be able to cope with disease and death guided by his own medical adviser, without the intervention of an army of medical officers of health and sanitary inspectors and without consigning his nearest and dearest to the tender offices of strangers in a public hospital.

State management being a dangerous experiment, what ought to be the relation of the civil power to that part of the country as long as it continues to contribute, not only for the help of sick paupers, but also, as has been shown it does, in the Highlands and Islands of Scotland for the whole existing population in those poor and remote regions? Fortunately, we have been provided with an answer to this question by the successful results of the action of the Scottish Education Department in parallel circumstances. In the Island of Lewis where on account of the poverty of the population the department found it necessary to give exceptionally large money grants to the schools "my lords" insisted on exceptional powers of interference in the local management of those schools. H. M. Inspector has a seat—indeed, the chief seat—on their boards; regulates the appointment and dismissal and pay of all teachers, and really controls the whole management. In like manner, wherever there are exceptional grants, say above 20s. per head for each individual on the roll of paupers in such parishes, the Scottish Local Government Board should have the right to appoint one of their inspecting officers to a seat on the parish council with the right of voting on the appointment, dismissal, and salary of the Poor-law doctor. The position, status, and security of tenure of the teachers have been much improved by this system of modified State interference and so, there can be no doubt, would also be the result in the case of parochial medical officers in the Highlands and Islands. Petty saving and petty tyranny would disappear and we would by-and-by have a contented body of well-paid, well-housed, and properly free and independent public servants. At present the Poor-law service is often the very opposite, to the detriment not only of the medical care of the poor but also to the loss and misfortune of those who are better off.

I might enlarge on the need for holidays and, above all, for pensions. But I have said enough at present to show the urgent need for reform. The first step mentioned, that of Government interference, could, I believe, be at once effected by a modification of the regulations for the granting of Poor-law medical relief in exceptional cases, and along with this change should come, in simple justice to Scotland, not a fixed annual contribution from the Consolidated Fund for the whole of that part of the kingdom as at present, but a frank payment of the one-half of each parish doctor's salary as has long been the case in England, while the proportion, I believe, is still more in Ireland.

I am, Sirs, yours faithfully,

WILLIAM BRUCE.

Jan. 1st, 1907.

in medical prescription or otherwise, in any preparation which can be used as a beverage, or which is capable of being taken internally as a medicine, and the use of methylated spirits in making any other preparations should receive the sanction of the Board before they are made up." This reply refers, of course, to ordinary mineralised methylated spirit but it reveals a willingness on the part of the Board of Inland Revenue to consider special cases. Hence it would be well if secretaries of hospitals were to write to the Board for permission to employ industrial methylated spirit for external applications not mentioned above.

I am, Sirs, yours faithfully,

"HESPERUS."

Jan. 5th, 1907.

SIR WALTER SCOTT ON "EUGENICS."

To the Editors of THE LANCET.

SIRS—Old writers are sometimes unconsciously instructive upon topics supposed by us moderns to be peculiarly of to-day. Thus Sir Walter Scott in "The Pirate," one of his less-known works which is full of good psychological analysis à la Thackeray, devotes a long excursus to the subject which during the last year or two we have agreed to call "eugenics." It is the aim of "eugenics" to breed human beings as pedigree dogs and horses are bred. The idea commends itself to a generation as much in love with ideas of State interference and machine-made human institutions as it is ignorant of the long teachings of history and of human nature. Sir Walter Scott is speaking of the queer discrepancies everywhere apparent, as well now as in his day, in the marriage relation. How is it, he asks, that such unlikely people are constantly found mated together? How is it that the short man marries the tall woman and that the idealist becomes the husband of the practical housewife? Scott answers the question in his wise, old-fashioned way: "A moral and primary cause might be easily assigned for these anomalies, in the wise dispensations of Providence, that the general balance of wit, wisdom, and amiable qualities of all kinds, should be kept up through society at large. For, what a world were it, if the wise were to intermarry only with the wise, the learned with the learned, the amiable with the amiable, the gay, even the handsome with the handsome?" It would be the world dreamt of by the Eugenic Utopians, who would further, by Socialistic State enactment, endeavour to prevent all the other people becoming parents. Scott as a shrewd man of the world does not entertain the possibility of such prevention for a moment. Indeed, he knows nothing about it, though he writes in 1831, an age familiar with revolutionary schemes and visions even wilder than our own. "And, is it not evident," he continues in his hearty reasonable way, "that the degraded castes of the foolish, the ignorant, the brutal, and the deformed (comprehending, by the way, far the greater portion of mankind) must, when condemned to exclusive intercourse with each other, become gradually as much brutalised in person and disposition as so many orang-outangs? When, therefore, we see the 'gentle joined to the rude,' we may lament the fate of the suffering individual, but we must not the less admire the mysterious disposition which thus balances the moral good and evil of life:—which secures for a family, unhappy in the disposition of one parent, a share of better and sweeter blood, transmitted from the other, and preserves to the offspring the affectionate care and protection of at least one of those from whom it is naturally due." The whole passage suggests a very real reconciliation between the argument from Design and the argument from Darwin.

I am, Sirs, yours faithfully,

Q. A.

FREE FEEDING OF SCHOOL CHILDREN AT MARSEILLES.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

The Menu, the Cooking, and the Cost.

THERE are not many children fed at the *cantines scolaires* of Marseilles but those who are fed are well fed; also whatever is done is fully recorded. Thus at the town hall I was supplied with these figures: "School population on July 21st, 1905—boys, 19,265; girls, 19,723; maternal schools (that is to say, schools for children from three to six years old of both sexes), 9,773; in the crèches, 275

babies; total, 48,753." In regard to the feeding the last complete statistics are for the year 1905, and these show that 1693 boys frequented the *cantines scolaires*, 1473 girls and 1950 children under six years old attending the maternal schools. This makes a total of 4632 and as the school population was much the same in numbers as it is now this is equal almost precisely to 10 per cent. of the whole. Thus, at Marseilles 90 per cent. of the school children return home for their meals and of the 10 per cent. who avail themselves of the school repast a large proportion—namely, a small half—pay for their food. The following are the exact figures and they are instructive as indicating what the organisers of midday meals in the primary schools of a large seaport town may expect. The number of helpings of soup served to boys during the year amounted to 224,271; of these 117,473 were given gratuitously and 106,798 were paid for. The girls received a little less—namely, 217,363 helpings of soup. They, however, paid for a much larger proportion—namely, 118,522—and only received 98,841 gratuitously. In regard to the schools for little children, or maternal schools as they are called in France, the figures are very different, not only at Marseilles but wherever I have been able to make the comparison. The practice of feeding in the maternal schools is much more general and the extent to which this is done gratuitously is widespread. Thus, instead of only 10 per cent. availing themselves of the *cantines scolaires* we find 1750 out of 9473, or more than 18 per cent. They also received a greater number of helpings, though this can be explained by the fact that at the maternal schools nothing but soup is given and that the children are too young to go home alone in the middle of the day, while at the other schools there are regular dinners with meat, vegetables, &c. The number of helpings of soup served at the maternal schools is set down at 371,563, but what is more important than this large figure, for which an explanation has just been given, is the fact that of all these helpings only 59,227 were paid for and the remaining 312,241 were given gratuitously. Whereas at the boys' and girls' schools the parents managed to pay for more than half the helpings of soups given not one-sixth of those served in the maternal schools were paid for by the parents of the children. This is very natural. The principal use of a maternal school is to offer a shelter to little children while their mothers are at work. Of course, it is only among the poorest sections of the community that the mothers have to work as well as the fathers.

In most, if not all, of the *cantines scolaires* established in connexion with the schools for boys and girls not only soup but a regular meal is provided. As a rule, most of the children have the entire meal but some take the soup only and others do not have soup but only take the courses that follow. These latter in the statistics come under the general heading of "portions." The difference is but slight; thus it has been stated that the boys consumed a total of 224,271 helpings of soup and to this figure I can now add that they also had a total of 225,878 "portions" and they paid for 117,349 of these portions, receiving 106,529 gratuitously, thus again paying for the larger half. The girls consumed 216,276 portions, or 337 portions less than in the case of the soup, while the boys took 1637 more portions than soup, showing a slight preference on the part of the boys for solid as opposed to liquid food. But again the girls were ahead of the boys in regard to payments for they only received 93,925 portions gratuitously and paid for 118,051 portions. Taking the grand total there were in the maternal schools and in the boys' and girls' primary schools 4832 children who during 1905 received soup from the *cantines scolaires*; they paid for 284,648 helpings of soup and did not pay for 528,554 helpings of soup, making a total of 813,202 helpings of soup provided by the *cantines scolaires* in the year. Deducting the 1750 children fed at the maternal schools where only soup is given there were 235,400 portions served to the boys and girls in the primary schools which were paid for and 207,454 which were not paid for, making a total of 442,854 portions. Adding the 613,203 helpings of soup, we get the grand total of soup and portions amounting to 1,256,056. Of these 520,648 were paid for by the parents of the children and 735,408 by the municipality.

The by-law or *règlement* under which the *cantines scolaires* are organised by the municipality bears the date of June 22nd, 1833, and was drawn up and adopted when Dr. Flai-sières was mayor of Marseilles. As a doctor of medicine and a sanitary reformer Dr. Flai-sières naturally appreciated the importance of securing sufficient food for the children.

Size of rooms.—We think this is important and must be taken into account in considering the results of the tests. It does not, however, in any way invalidate these results.

Carbon dioxide.—The amount of CO_2 found in the rooms was small and very slightly increased above that in the air admitted. Why should the CO_2 be increased if all the products of combustion are carried up the flue? Our observations showed that the ventilating effect of the stoves was considerable. Mr. Jones does not state what was the ventilating effect of his stove.

Carbon monoxide.—There were three cases when this was detected in the room; one was a flueless stove, another was proved to have some defect in the joints, and the third case was probably also due to a leaky joint. These were exceptions, to be condemned individually, but not to base an adverse general conclusion upon.

Potassium permanganate test.—The dust somewhat vitiated this test. Its results were chiefly negative and not satisfactory as a basis of comparison; no conclusion was therefore drawn from it.

Smell.—Although many stoves caused a smell the fact that in 12 cases it was absent showed that smell is not an invariable accompaniment of gas stoves and is avoidable by proper construction.

Humidity.—The actual humidity of the room air is no guide as to the effect of a stove or fire unless it is compared with that of the air before admission to the room. It was upon the alteration of humidity, therefore, that conclusions were based. In Mr. Jones's tests the temperature produced in the room with the gas fire was higher than that due to the coal fire, he does not state how much; but it is important to note that a difference of 4°F . would more than account for the difference of humidity which he found between the gas and coal fires.

Musk plant test.—No conclusions as to the merits of the stoves were drawn from this test.

In conclusion, Mr. Jones's experiments were carried out in a very small room, of 935 cubic feet capacity, the air of which was obviously vitiated from some source other than the stoves, since the CO_2 often exceeded 10 parts in 10,000 in the morning, and averaged 3.039 in excess of that in the outer air, without any stove or fire in the room. The amount of air passed through the room per hour is not recorded by Mr. Jones, a serious omission; but it would seem from his results that the ventilation was deficient. Further, it is essential (a) to determine where the air drawn into your room comes from, and (b) to apply all the tests to the air before admission which you apply in the room. Otherwise the results are of little value. Mr. Jones did not do this.

It is to be noted that the conclusion drawn from the Coal Smoke Abatement Society's inquiry was not that all gas stoves are good, but rather that there is no inherent necessity why a gas stove or fire should not be as good as, or even better hygienically than, a coal fire, provided it is intelligently constructed and properly fitted to a good flue.

We are, Sirs, yours faithfully,

H. A. DES VOGES, M.D. BRUX,
Honorary Treasurer, Coal Smoke Abatement Society.
JOHN S. OWENS M.D., A.M. Inst. C.E.,
F.R.G.S.

MEAT DIET AND THE TEETH.

To the Editors of THE LANCET.

SIRS,—I shall be obliged if you will allow me briefly to supplement the remarks made by Dr. Chalmers Watson in THE LANCET of Jan. 12th in reply to a letter by Dr. J. Sim Wallace which appeared in the issue for Jan. 5th. This most interesting investigation is still incomplete but is sufficiently advanced to justify one in publishing some general conclusions which may assist others working along similar lines.

In the first place, one is struck by the essential similarity in the pathological changes occurring in the teeth of rats and of man. In the three rats referred to by Dr. Chalmers Watson the teeth presented all the characteristics of "honey-combed teeth" seen in children who have been improperly fed; and microscopically, too, allowing for natural differences in the histology of the teeth, the defects were similar to those found in honeycombed teeth in the human subject. One would almost feel inclined to apologise to those acquainted with comparative pathology for pressing this matter of the essential similarity of pathological processes in animals and in man, did one not often meet with critics who deny it, although they unhesitatingly accept the principle of the similarity of physiological function.

The second noteworthy fact is that in spite of the striking alterations present in other organs of rats fed on a meat diet the teeth show no evidence of having suffered. This is what any dental physiologist would have expected and should afford food for reflection for those who are lamenting the "degeneracy of the teeth" of the present day. I have for several years had unique opportunities in studying this question in the class of patient who would be most likely to show signs of degeneracy and the results of these experimental investigations have strengthened my conviction that there is no evidence whatever of any "degeneration of the teeth" at the present time. We must, therefore, in my opinion, look in other directions for the cause or cause of the increased prevalence of caries.

I am, Sirs, yours faithfully,

Edinburgh, Jan. 13th, 1907.

J. H. GIBBS.

To the Editors of THE LANCET.

SIRS,—Dr. Chalmers Watson contends that a dietary deficient in lime salts does not make the teeth susceptible to caries and that the facts ascertained from his investigation support the teachings of Dr. J. Sim Wallace on this subject. If this be so, it would be well to know further whether the artificial feeding of infants prejudicially affects the teeth, and whether it is true that artificially fed children are specially susceptible to dental caries as has been contended.

I am, Sirs, yours faithfully,

Kingston-on-Thames, Jan. 13th, 1907.

W. GEO. CRESTWELL.

TUBEROSE SCLEROSIS OF THE BRAIN.

To the Editors of THE LANCET.

SIRS,—I have read with some interest the letter from the editor of *Brain*, published in THE LANCET of Jan. 12th, 1907. He is incorrect in supposing that Dr. A. W. Campbell's work is "apparently unknown" to me. I am well acquainted with Dr. Campbell's paper on Cerebral Sclerosis, published in *Brain*, 1905, and the fact that the case of tuberoze sclerosis occurring at the West Riding Asylum, Wakefield, differed in some important respects from the similar cases described by him was the chief reason that made me send my account of the case to THE LANCET for publication.—I am, Sirs, yours faithfully,

MARGARET B. DOBSON, M.D. Lond.,

Pathologist to the West Riding Asylum, Wakefield.

Jan. 14th, 1907.

DUTY-FREE ALCOHOL FOR MEDICAL PURPOSES.

To the Editors of THE LANCET.

SIRS,—May I be permitted to correct one or two errors in your annotation under the above heading in your issue of Jan. 5th, 1907, p. 40. Your correspondent is in error in stating that the new grade of methylated spirit, "industrial methylated spirit," is "undenatured"—namely, unmixed with naphtha. The Revenue Act, 1906, provided, it is true, for the omission of the three-eighths of 1 per cent. by volume of mineral naphtha in industrial methylated spirit, but at the same time the wood naphtha was retained in smaller proportion, the new spirit containing the one-nineteenth part of wood naphtha instead of the one-ninth part as contained in ordinary methylated spirit. The suggestion made by your correspondent that medical men should be allowed to employ industrial methylated spirit for external use has been in part anticipated by the Inland Revenue authorities, as the new Act provides for its use in the composition of soap, compound camphor, aconite, and belladonna liniments of the British Pharmacopoeia. It remains to be seen whether the presence of 5 per cent. of wood naphtha in industrial methylated spirit will confer on the spirit the irritating properties that are associated with ordinary methylated spirit. If the new spirit should prove to be irritating the matter might be brought to the notice of the Inland Revenue authorities, who might allow a further reduction in the proportion of wood naphtha present or permit the employment of some other denaturing agent. An inquiry has recently been addressed to the Inland Revenue authorities as to whether it is permissible to use methylated spirit in preparations for outward application if methylated spirit is prescribed by a medical practitioner. The secretary to the Board of Inland Revenue replied "that it is illegal to use methylated spirit."

cantine scolaire and which was given to what in England would be described as pauper children. My visit to the Marseilles *cantines scolaires* helps to explain how this has come about, for here the poorest section of the population are taught how to render the refinements of the table accessible to all. Artistic cooking is not a question of money but of good taste, of skill, and of painstaking. It can therefore be applied just as well to a dinner of three courses costing only 1½d. as to an extravagant banquet. But, then, everyone in France is more or less a cook and takes a genuine and technical interest in the matter. The head-master at the rue Puget school had spent hours in discussing menus with the *cantinière*. Such discussions were not necessary so far as the service was concerned but were pleasant and interesting to both parties. Personally, I raised the question of finance, for 1½d. seems a very small sum for a full meal. Thereupon the head-master began to dictate what an *ordinaire* for 50 boys would cost. Beef he put down at 24 sous the pound. It is curious that at Marseilles more than at Paris the people still talk of sous. Three kilogrammes would therefore cost 3 francs 60 centimes. Then there might be one kilogramme of Italian pastes, 50 centimes; six kilogrammes of potatoes, 60 centimes; half a litre of oil to bake the potatoes, 50 centimes; salad, 40 centimes; and flavouring ingredients, 25 centimes. This makes a total of 5 francs 85 centimes and would be enough for 50 pupils who at 15 centimes each would pay 7 francs 50 centimes, so there would be a surplus of 1 franc 65 centimes remaining in hand. Yet the 3000 grammes of meat divided by the 50 pupils would give 60 grammes to each pupil or ten grammes more than the amount stipulated in the by-law. As the meal costs less than 1½d. there is a large margin for the purchase of a better quality of meat, 6d. a pound being a small sum to pay for beef. But then, as explained above, this inferior quality of beef is rendered tender and tasty by the method of cooking.

At the Rue Puget school the 60 boys who remained for their midday meal were, I was informed, for the most part children of shop assistants and small tradesmen. On that day 13 of them were not able to pay for their food and had free tickets from the municipality. The master regretted that a greater number did not dine at school where the meals are better, cheaper, and cleaner than those which the children generally had at home; moreover, he insisted that appetite was contagious and the weakly, delicate children who did not care for their dinner ended by following the example of the more robust and, if only for the sake of getting back to the playground, managed after all to eat their food. This was less likely to be the case if they went home. It was not only a question of feeding the hungry but of enticing those who were not hungry to eat what was necessary for their sustenance.

At the girls' communal school of the Rue St. Savaornin there was a meal on the day of my visit that reminded me a little of English extravagance. There were 40 girls and they each had a small, plain, fried beefsteak; there was no sauce, nothing whatsoever to disguise the lack of flavour or the toughness of the meat. Consequently, it being necessary to buy more expensive meat, two and a half kilogrammes of steak at 2 francs per kilogramme had been purchased. This made 5 francs for the 2500 grammes of raw meat which being divided amounted to 62 grammes, or barely more than two ounces of uncooked steak for each of the 40 pupils. But 40 times 15 centimes only make 6 francs, so there did not remain more than one franc for the rest of the dinner. Evidently too much had been spent on the meat. Two francs a kilogramme is equal to 16d. a pound of 500 grammes, whereas the English pound is only equal to 450 grammes; the cost may therefore be translated as equal to 9½d. the pound, and steak obtained in England for that price is not likely to be particularly succulent or tender. The really good part of this dinner was the fried potatoes and the salad that accompanied the steaks. But the oil for frying the potatoes doubtless cost 50 centimes and it was the oil that imparted to the potatoes their beautiful golden colour and their crisp, delicate crust. Then the salad must have amounted to another half franc, while the seasoning, the traditional three parts of olive oil to one of white wine vinegar, together with suitable herbs, must have cost as much again. The potatoes and the salad for the 40 pupils must have necessitated an outlay of at least another 2 francs, so that with the steak at 5 francs this made 7 francs or more. Thus I conclude that the attempt to give a steak, however small

and inferior in quality, meant a deficit of at the very least one franc, or an expenditure of 20 per cent. more than the receipts. Above, however, I have shown how a satisfactory and much more artistically cooked meal can be given for less than 15 centimes a head. Doubtless an occasional change is beneficial and what is economised on the one meal can be spent on the other. Thus it sometimes comes to pass that the children are given a plain piece of steak but such extravagance is the exception, not the rule.

MILK IN SMALL GENERAL SHOPS.

(FROM A CORRESPONDENT.)

I.

THE question of the milk-supply of England in general, and of London in particular, has been widely discussed in recent years. It has been shown that the methods usually employed on dairy farms as regards the conveyance of milk by train and its distribution after arrival in London or other great towns are all susceptible of much improvement. The fact, however, undoubtedly remains that, although progress towards insuring a satisfactory milk-supply has been made, there is still need for far wider and more radical reforms in this direction. The problem of obtaining a milk-supply comparatively free from pollution is one that must be met in all the stages through which milk passes from the cow to the consumer. At the present time I shall merely consider somewhat briefly the milk question from the standpoint of its sale in small provision shops. Of course, it is obvious that milk is frequently badly polluted before it reaches the small retailer, but that is no valid reason why precautions should not be taken to guard it from contamination whilst it is in the shop. That such precautions are not generally taken has been freely stated in medical and lay journals during the past few years. The ordinary individual and, to some extent, the medical man, have little idea of how largely milk is sold in small general shops in all parts of London. The statement has been made on excellent authority that about 70 per cent. of the total milk-supply of London is to be found in the small shops. That being so, it is a matter of infinite importance that all due care should be taken to safeguard the food on which the greater part of the bottle-fed infant population in the poorer quarters of large cities should chiefly depend for nourishment, though it is probable that a considerable amount of the milk given to the poorer class of children is a condensed milk of one sort or another.

In order to convince myself as to the conditions prevailing in small general shops in poor localities in which milk is sold I determined to make a short tour of inspection through a few of the poorest parts of London. I must, however, disavow any intention of treating the matter from a scientific point of view; my object was simply to use my senses of sight and smell to the best of my ability and to gather general impressions, perhaps, rather than to gain any very definite details. It struck me at once that the East End was obviously the district where the greatest number of poor was gathered together and that there I should be able to observe in most favourable circumstances the manner in which the retail milk trade was conducted. I accordingly betook myself to that maze of mean streets and monotonous drabness known as the East End and selected for my first series of observations a well-known street not far from the goods station of the Great Eastern Railway in Shoreditch. The portion of this street through which I passed may be described, I suppose, as typical of that part of London—that is to say, it is dirty, dull, and equalised. The monotony of the houses is only relieved here and there by conspicuously glaring public-house fronts, while numerous small general shops are characteristic features of the neighbourhood.

The first shop into which I entered was about 18 feet long by 14 feet wide and fairly lofty. It was furnished with a counter on one side stretching from the door almost to the end of the room. The shop was packed with a heterogeneous mass of goods, mainly eatables, but intermingled with these were other articles of domestic use, as firewood, paraffin oil, and matches. The contents were scattered in all directions, on the floor, on shelves, while the counter was crowded with a variety of miscellaneous articles, not omitting samples of fish. The door of this establishment stood wide open, so that dirt and dust had free ingress, and judging

At that time, some 13 years ago, there were only three or four schools where meals were provided and these were only given in exchange for payment. Further, such endeavours were absolutely voluntary, untrustworthy, and uncontrolled. So it was decreed that municipal *cantines scolaires* should be established wherever there was reason to believe such "an institution would respond to the needs of the working population." The municipality undertook to provide all the material necessary, an inventory would be drawn up, and the directors of the schools would be placed in charge of this property. Each *cantine* would have a *cantinière* nominated by the mayor and placed under the authority and direct control of the head of the school. A committee of 22 members would be appointed by the mayor, presided over by the mayor or his representative, and would examine the demands made by the families who stated that they were unable to pay for the feeding of their children while at school. The *cantinière* or cateress is paid £1 12s. per month as wages. One of her duties consists of warming whatever food the children may bring with them and she must on no account accept any sort of payment from the children for any such service.

This latter is an important consideration. Parents may be able and willing to supply their children with food but if the children bring such food with them it must of necessity be cold. At Marseilles such food may be warmed free of any charge whatsoever. As the community supplies the entire school gratuitously to the children, including the services of the teachers, it was not considered a very great effort to add the services of the *cantinière* and a small space in the kitchen stove to warm the meals. Apart from the midday meal the *cantinière* may sell to the children chocolate and dried preserved fruits but not the ordinary sweets which children hanker after though they are often far from wholesome. The by-law has articles enforcing absolute cleanliness in the kitchen and in regard to all the utensils used; moreover it enters into the detail of the weekly menu. Thus it is stated that on Monday there shall be "lean" soup—that is to say, soup in which there is no meat—but with rice, beans, peas, lentils, oil, or butter it may be nutritive and substantial, while it is rendered tasty by the variety of vegetables used together with aromatic and flavouring herbs. Then follows a *ragoût*. This is a generic term for meat braised or stewed in conjunction with other, generally vegetable, ingredients. On Monday this stew, it is proposed, should be made of the neck or breast of mutton, with potatoes, haricot beans, or Italian paste of the macaroni kind. On Tuesday, instead of a lean (*maigre*) there is to be a fat (*grasse*) soup—that is to say, a soup made with meat, probably the national *pot-au-feu*, or beef slowly simmering in a great variety of vegetables, with burnt onions to colour and thyme and garlic to flavour. Thus a beef soup is obtained which is not insipid like English beef-tea. Then follows the beef itself, not the stringy, tasteless fragments of beef which remain after beef-tea or soup has been made in an English kitchen and which are only fit to be thrown to the dogs but good meat from which firm slices can be cut. As this meat is impregnated with the flavour of numerous vegetables it is savoury though it is only boiled beef. Of course for this purpose prime pieces such as the sirloin are not employed. On the other hand, if the inferior pieces of beef were roasted, as is very generally the custom in England, they would be tough and tasteless. By the above process the meat is rendered at once tender and tasty though only the cheaper pieces or joints are used. Very generally some of the vegetables from the soup are served with the beef when hot. This, indeed, is the French national dish. *Bouillon et bœuf* are to the Frenchman what roast beef and Yorkshire pudding are to the Englishman. The British fare is good when the quality of the beef is good; but the French fare is good even when the quality of the beef is inferior. This is an all-important consideration as everyone cannot be fed on prime joints; the cheaper portions must also be consumed especially where economy is necessary. Thus, though meat is very dear in Paris, at all the ordinary workmen's restaurants an *ordinaire* can be obtained for 4d. This is the usual name given to a plateful of *bouillon* followed by a large thick slice of the beef with which the *bouillon* has been made. The meat is accompanied with some of the vegetables if it is hot, or pickled gherkins or the like if cold. By spending 4d. or 5d. more, wine, bread, and cheese can be obtained, and thus for from 8d. to 9d. the workman has a substantial if a very

plain meal. On a smaller scale this is the sort of suggested in the Marseilles municipal by-law for the *cantines scolaires* on Tuesdays. Evidently it is calculated that amount of beef employed will not make soup for two days on the Wednesday there are vegetable soup, macaroni, and probably braised or fried. Thursday is the weekly hot day. On Friday there are another vegetable soup and a *ragoût* whatever meat may be preferred, and on Saturday we again the *ordinaire*—namely, the *bouillon* and the beef, the vegetables with which it has been made. Now comes an important question of the quantity. This also is specified by the by-law. The helpings of soup, whether vegetable meat soups, are set down at 30 centilitres, or half a pint. The meat, whether in the form of boiled beef or a steak given in portions of 50 grammes, or one and two-thirds ounce; with half a pint of potatoes, haricot beans, lentils, or other vegetables. Latitude is allowed to modify this according to the season of the year and the charge is 5 centimes for the soup and 10 centimes for the portion of meat, that is 1½d. for the entire meal; but in the 10 schools frequented by older children it is allowable to add a little more for larger helpings.

All the police stations at Marseilles keep paper tickets, or cheques which the parents of the neighbourhood and give to their children. These are collected by the *cantinière* the first thing in the morning and given to the *cantinière* then knows how many meals she must prepare. If, however, a child arrives at school without a cheque for a meal the teacher thinks he needs food the teacher may give provisionally. The teacher must then at once communicate with the parents and the town authorities. The parent may apply personally or by writing to the educational committee at the town hall. Their case is investigated and it is thought that they are entitled to free meals for their children they receive the cheques directly from the municipality instead of having to buy them at the nearest station. When, however, the child arrives at school he knows whether the cheque which he holds in his hand has been bought and paid for or has been received gratuitously by the parents. Thus at Marseilles, as at Paris and elsewhere, the greatest precautions are taken not to harm the children. The cateress has to enter in a book, and keep a careful account of, all her purchases and all the helpings of soup or meat which she has served. Every fortnight she must present her books at the town hall and then the cheques which she has received for meals are converted into cash. The money which she thus receives must be applied on food and not on any kitchen utensil, or fuel, or washing dishes, or any other item. Thus it will be seen that a considerable portion of the cost of the meals is paid by the municipality even when the parents purchase the cheques for their children. Moreover, the 22 members of the committee are supposed to pay surprise visits at meal times and to weigh at least five portions and thus to verify the proper amount is given.

When I was at Marseilles I visited the communal school for boys in the rue Poget. This is an old house not expressly for a school. The room where the meals are served gives on to the play yard and is rather dark. The tables were covered with tin which was easy to keep clean. There were no *serviettes* as I had seen at the Paris *cantines*. Some 60 boys were at table; a few drank water but the majority had brought a little of the ordinary red wine of the country with them. They probably drank two ounces of wine containing 10 to 12 per cent. of alcohol, to which about 100 per cent. of water was added. A large proportion of these who were not able to pay for their meals were at least able to pay the fractional part of a farthing which so small a quantity of wine cost. On the day of my visit consisted of potatoes, followed by beef and macaroni. The latter was rather tasteless, insipid macaroni boiled in milk as served in England. It was *macaroni au gratin*. The water had been well drained away, then the macaroni was mixed with cheese, sprinkled with bread crumbs, and placed in the oven till it had a golden, crisp, and tasty crust. The beef was lean, cut into portions before it was cooked and then served with a sauce that was a real work of art. I had just arrived from Gibraltar having travelled on board a well-known P. & O. steamer. Here as a saloon passenger I was supposed to enjoy every refinement and luxury. But I am bored and I would have been very glad to obtain a

Apart from Christian or even merely humane motives the lives of these hapless waifs should be jealously guarded. In these days of a steadily decreasing birth-rate and of high infantile mortality they are of value to the State; they are assets which the country cannot afford to throw away, especially in the face of such statements as that which appeared the other day of a Lincolnshire district where the infantile mortality was 267·7 per 1000 births.

Jan. 15th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Milk-supply of Cardiff.

At the last two meetings of the Cardiff health committee it has been alleged that there is a considerable amount of milk sold in Cardiff which has been diluted. The milk churns are said to be tampered with at the railway station, and as there is only one inspector who is authorised to take samples it is apparently not difficult for the milkmen to watch his movements and thus to escape detection when systematically impoverishing the milk either by actually diluting it with water or by mixing a supply with skimmed or separated milk. In order to enable the committee to decide as to whether the Sale of Food and Drugs Act was being properly carried out in Cardiff Dr. E. Walford has submitted a report which shows that when compared with other large towns in England and Wales the number of samples per 1000 of the population taken for analytical examination is rather higher in Cardiff than elsewhere, while the proportion of adulterated articles is very much below the average. For example, in 1905 out of 388 samples of milk taken in Cardiff only 14, or 3·6 per cent., were adulterated, while in the administrative county of Glamorgan 7 per cent. of the samples examined were adulterated and in the neighbouring borough of Newport about 10 per cent. of the samples examined are found to be adulterated. Dr. Walford suggests that the assistant inspectors of nuisances should be appointed to act as inspectors under the Act and be thus enabled to take samples. In order to carry out this suggestion it will probably be necessary formally to appoint them in the first instance market inspectors, a procedure which has been adopted in Newport. If a sufficient number of inspectors are appointed, and if they are provided with bicycles to enable them to travel speedily from one part of the town to another, there ought to be no difficulty in carrying on a vigorous campaign against the defaulting milk vendors and insuring a pure supply of milk to the inhabitants.

River Pollution in Monmouthshire.

Among the duties imposed upon sanitary authorities is that of administering those Acts of Parliament which have for their object the prevention of the pollution of rivers. As a rule, they are not particularly active in carrying out this duty and their apathy is, no doubt to a great extent, accounted for by the fact that they are themselves only too often the greatest offenders against the provisions of the Acts. It is not surprising to find, therefore, angry protests from local sportsmen when a river celebrated for its fishing is being polluted. In the annual report of the board of conservators of the rivers Uck and Ebbw in Monmouthshire attention is drawn to the serious pollution of the Uck by the corporation of Newport. Samples of water taken from streams and tributaries of the river have upon examination revealed the existence of serious pollution both by sanitary authorities and from works situated on the banks of the streams, in one instance the stream being practically an open sewer. The Board of Agriculture and Fisheries has been communicated with by the conservators and it is anticipated that some steps will now be taken to lessen the pollution.

Housing of the Working Classes in Newport.

A recently issued report of Dr. J. Howard Jones, the medical officer of health of Newport (Mon.), contains statistical information of much interest relating to the housing of the working classes. He has collected details respecting 1760 cottage houses, including the rental paid and the number (1) of rooms in each house, (2) of inhabitants distinguishing between adults and children, (3) of families occupying the house, and (4) of the lodgers taken in. The

average weekly rental was found to be equal to 1s. 5d. per room. The average number of persons per house was in one district 7·5 and in another 6·64. The average number of persons per room was 1·14, a satisfactory feature when it is remembered that the Registrar-General suggests that a standard of overcrowding should be where there are more than two inhabitants per room. A little more than one-half of the total number of houses were found to be occupied by more than one family and in about 7 per cent. lodgers were taken in.

Bristol University College, Colston Society.

The eighth annual dinner of the Bristol University College, Colston Society, was held on Jan. 11th in the lecture hall of the college under the presidency of Sir William S. Church, Bart, K.C.B. The Colston Society has been instrumental in rendering useful financial help to the Bristol University College and has also done much to draw public attention to the scheme for a West of England university, with Bristol as the centre. The Lord Mayor of London, Sir W. Anson, M.P., the Vice Chancellor of the University of Oxford (Mr. H. Warren), and Mr. Henry Hobhouse were among the speakers, and they all advanced strong arguments in favour of a university for Bristol. The collection amounted to £489, the second highest which the society has had.

Sanitary Matters in the Tavistock Rural District.

At a meeting of the Tavistock rural district council held on Jan. 10th certain statements made by Dr. R. Deane Sweeting, a Local Government Board Inspector, with respect to the sanitary condition of the district were considered and the chairman presented a report which took the form of a detailed reply to Dr. Sweeting's criticisms. The circumstances have been already mentioned in THE LANCET. The chairman's report stated that the council was willing to carry out Dr. Sweeting's recommendations in reference to disinfection, and in conclusion requested the Local Government Board to sanction the appointment of Mr. O. O. Brodrick as medical officer of health for the ensuing year, as the council was quite satisfied with the manner in which his duties were performed. The council adopted the report and decided to send a copy to the Local Government Board.

Sir Squire Bancroft at Yeovil.

Sir Squire Bancroft recently gave a recital of "A Christmas Carol" at the Yeovil Assembly Rooms in aid of the funds of the Yeovil Hospital. Sir Spencer Ponsonby Fane, who presided, said that Sir Squire Bancroft's charitable endeavours had now realised £15,600.

Jan. 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh Annual Report.

The annual report of the University of Edinburgh for 1906 has just been issued. The total number of matriculated students was 3199 (including 463 women), the highest number reached for 13 years. Of the total 1500 (including 16 women) were in the Faculty of Medicine; and of this number 681 belonged to Scotland, 301 were from England and Wales, 136 from Ireland, 82 from India, 272 from British colonies, and 23 from foreign countries. The number of women attending the special school for women with a view to graduation in medicine was 71. The number who graduated was 167 (including 17 women). The number of graduates who took the M.D. degree was 90 (including two women). The diploma in tropical medical and hygiene was conferred on five candidates, while the special certificate in diseases of tropical climates was conferred on 60 candidates (including eight women). The total annual value of fellowships, scholarships, bursaries, and prizes in the Faculty of Medicine amounts to £3630. A sum of £600 per annum is available for the encouragement of original research. Under the paragraph devoted to the Carnegie foundation it is noted that it has so far not effected a marvellous increase in the number of students but that it continues to be noticeable that many who avail themselves of the section of the scheme which provides for the payment of class fees take out a larger number of classes than they would probably otherwise have done. Personal charges in the professoriate and in the names of lecturers are given in detail, but these have been noted in THE LANCET at the time when the charges were

from the littered state of the street outside the prediction may be made confidently that in dry weather a plentiful supply of dust and of even more objectionable varieties of dirt would be carried in past the door in no inconsiderable quantities. The milk, contained in an ordinary tin pail, had its place amid this promiscuous heap of provisions and household supplies of various kinds, in close proximity to the open door and consequently in the most convenient situation to collect any atoms which might float in. In this instance the milk was partially covered, but inasmuch as the cover did not fit closely but left sufficient space on all sides for any quantity of foreign matter to gain an entrance, it might as well have been dispensed with. It cannot be said that the shop in itself was especially dirty nor was it clean enough to clash with its environment. The persons, a man and a woman, who served in the shop were by no means personally clean. I was not near enough to observe whether the milk pail was clean, but I did notice that the dipper was placed on the cover when not in use, thus affording ample opportunities for it to collect extraneous matter, some of which would be afterwards conveyed to the milk.

The next shop to which I paid a visit was situated a few doors from the first one and was in most respects in a worse sanitary state. It was much smaller, more dingy, and more overflowing with eatables and otherwise. This shop cannot have been longer than 12 feet and in width was about 8 or 9 feet. It was low in the ceiling and in most of its external aspects presented a decidedly grimy appearance. The shelves and the counter were heaped with many varieties of articles necessary to the small housekeeper. The milk was contained in an open receptacle and quite close to it, and almost on a level with it, was a dish of cured herrings. As in the former shop so in this shop—paraffin, firewood, and provisions were mixed together. In this case, too, the factor of personal cleanliness did not enter very intimately into the scheme of things. Of course, at this time of the year there were no flies in evidence, but one can imagine easily that in the sweltering days of midsummer such articles of food as fish and jam would attract flies in great numbers and that these would convey dirt to the milk, sometimes even dangerous germs. I visited two or three other shops of a like nature in the same vicinity, but the conditions of these differed only in degree from the two former shops which I had visited.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Meals for School Children.

At the last meeting of the Manchester city council it was proposed and carried that the Act of 1906 be adopted and that the details of providing meals for school children should be referred to the education committee. In speaking to the motion, Sir James Hoy thought it would probably be proposed to establish canteens in the worst districts and that payment should be charged at the rate of 1d. a meal. But as he said there would be many unable to pay these would not be left unfed. Members of the council of various political views seemed to agree on this question of feeding the children. In Manchester the cost is expected to be about £8000 a year, but as a rule these prophetic estimates are exceeded. One gentleman referred to some investigations by the Chorlton guardians, when out of 1295 applications relief was refused in 1000 cases. Sir James Hoy said the committee would try to ascertain the real cases deserving of their relief. Everyone sympathises with the children sent ill-fed and hungry to school and knows that the costly and elaborate compulsory education machine can only be run at a loss when those for whom it has been devised are in the apathetic and exhausted condition of semi-starvation. No doubt from the physical standpoint it will be good for the country that the next generation of men and women instead of being stunted and starved in childhood should have been well fed. But it is possible that the sense of parental responsibility and the ties of family may become so far relaxed that the physical benefit will prove to be purchased at a high rate.

Seamen's Sickness and the Port of Manchester.

On Jan. 7th the Manchester port sanitary authority discussed the subject of the notification of sickness on ship by the captains of vessels arriving at the docks. Recently a sailor who left a vessel at Salford had to be a few days afterwards to the Ladywell Sanatorium suffering from typhoid fever. No notification of the illness had meantime been given. Mr. W. F. Dearden said he was to devise a scheme for the notification of all cases of sickness and complained of the slowness of ships' officers as to matters. As was stated some time since, powers have been obtained for the inspection of food imports to Manchester and in view of the increased work this will entail it decided at the meeting to appoint two new inspectors.

Long Service.

The Macclesfield board of guardians has recognised great value of the services rendered by Mr. James Br Hughes by passing a resolution congratulating him on completion of 40 years as medical officer and public vaccinator. This is not his only claim to honourable mention; he is also Surgeon-Lieutenant Colonel 4th Battalion Cheshire Regiment.

Dangers to Infant Life: Compulsory Notification of Birth.

Blackburn is very properly concerned with schemes for the reduction of the high death-rate among infants, of which is the encouraging of the mothers to suckle their children. This has the especial approval of the local committee of the corporation which is going to appoint women sanitary inspectors. It is also seeking powers for the compulsory early notification of births. The mortality among infants in the districts where the women work till their confinement and get back to the mill as afterwards as they can creep about is not to be wondered at. No doubt, too, the mill or other work of the women with young infants leads to the great use of comforters, soothers, syrups, or whatever the opiate is called in the districts where they live. The briskest sale is where the women work at home. It is said that in Coventry about 12,000 doses of "soothing syrup" had been given to babies in one week and that in one Welsh colliery district three quart bottles of laudanum were sold every week for the same purpose. The strange thing is that so many survive. In an address to the women the other week at Preston Miss F. Zanetti, inspector to the Chorlton board of guardians under the Infant Life Preserving Act, who sees more than most people how heavily the babies are handicapped in their struggle to live through their first 12 months, after enumerating some of the dangers to be overcome or avoided, went on to say that the personal care and nursing of the child by its mother was the chief essential to its well-being and contrasted the high death-rate of 50 per cent. in the bottle-fed child with the 7 per cent. of those fed naturally by their mothers. During last year there had been on the register 18 cases comprising 49 children who had been nursed in 19 individual houses under the Act, and in all but three cases the nursing was satisfactory. There is one provision in which it might be some improvement. No matter how many children a woman nurses in succession, unless she has the care of one or more at the same time she does not come under the Act. This allowed of what had happened in Miss Zanetti's district—namely, that a woman who had been refused a licence had taken in two children, though not at the same time. These nurse children are seldom, if ever, taken from love or the pleasure of tending an infant but are a purely business matter to increase the family income. Miss Zanetti has sometimes been told that it paid the rent and rent collectors have been asked to wait a day or two "the child's money had not been sent yet." There is a certain amount, probably a good deal more than one might imagine, of profitable business done by the more astute of these women. One of them in Manchester had a child brought to her on the day of its birth, 7th week being paid for it. And though the child might seem slight it lived through its early days and was five months old was sent to a woman in Yorkshire who advertised for a baby. This person took it with a premium of £25 but like a clever financier she passed it on to another who took it for £20, so the Yorkshirewoman made money by the transaction. No doubt some of these women are humane and even tender, but recent revelations of children's calcined bones and so on show that the traffic in babies should be most carefully watched.

of Belfast Lough, due, it is said, to contagion by milk, while at Holywood, on the opposite side of the same lough, there is also an outbreak, which has been shown to depend on permeation of the surface soil in the affected areas with sewage matter due to defective joints in the sewers.

Citizens' Sunday in Belfast.

In Belfast on Jan. 13th special services were held in the various churches urging the importance of the citizens taking a more active part in the management of civic affairs. The rector of St. George's Church (Rev. Dr. H. D. Murphy) delivered a very able and outspoken sermon, in which he said that they could not avoid putting down to the corporation as a whole the charge of incapacity in managing civic affairs. He urged his hearers at the approaching municipal elections to give their votes to the man whom they considered upright, conscientious, and honourable, the man who had no private ends to serve, the man whom they would be prepared to appoint director of a concern in which they were shareholders.

Action of the X Rays on Gestation.

M. Sébilleau of Bordeaux has submitted doe rabbits after impregnation to the action of the x rays at various stages of gestation. Some of the animals had only one exposure of considerable duration, such as is used in radiography, while others had repeated exposures for various periods. The result of these observations was to show that whether there was only one exposure or a number of them the effect of the x rays was, if not to induce abortion, at least to retard the date of parturition and to inflict serious injury on the progeny, which exhibited a falling away from the normal vigour and weight in direct proportion to the number and length of the exposures. M. Sébilleau described his observations at a meeting of the Biological Society held on Dec. 22nd, 1906.

The Timorousness of Oriental Nations.

At a meeting of the Society of Hypnology and Psychology held in November, 1906, M. Damoglion said that in Turkey and Egypt timorousness constituted an endemic and hereditary mental condition. His investigations tended to show that this was due to a mental bias which has been developed as the result of a system of absolute and irresponsible despotism having reigned for centuries throughout all classes of society without distinction of race, nationality, or religion. Children had to keep absolute silence in the presence of their parents, young men in presence of their elders, apprentices in presence of their masters, and so on. Ever at the mercy of despotism and arbitrary treatment the Orientals lived under the domination of fear. Passive creatures, having no will of their own, no opinions, and no individuality, their timorousness too often rendered them addicted to lying, trickery, and hypocrisy.

Cancer of the Pharynx.

At a meeting of the Surgical Society held on Dec. 26th 1906, M. Hartmann read for Dr. Vallas a communication describing 19 cases of pharyngectomy for cancer of the pharynx. The results which he has obtained marked an improvement in methods of treatment. Among the 19 patients operated on there were 12 recoveries and seven deaths. In all the cases the lesions were extensive. A thesis by one of his pupils, who reported ten operations performed for cancers of limited area, mentioned that after the ten operations there were nine recoveries and one death. As sequelæ to the operations performed by Dr. Vallas there were three early relapses among the 12 successful cases, but with the remainder there was no recurrence until a period varying between three months and 10 or 12 months had elapsed. The mode of the operation must be in accordance with the extent of the lesions. In general a lateral slightly curved incision passing above the hyoid bone gave access to the seat of the disease; the subsequent steps of the operation must be determined by the circumstances of the case.

Complete Outward Dislocation of the Knee.

At a meeting of the French Society of Military Medicine held on Dec. 20th, 1906, M. Epaulard described a case of complete outward dislocation of the right knee. The patient was a soldier who had a violent fall from his horse during manoeuvres while it was at a gallop. The tibia was withdrawn from the femur for a distance of six centimetres. The part was not very painful except at the level of the internal condyle of the femur at a point corresponding to the insertion of the internal lateral ligament. Reduction was easily effected under chloroform and the patient was able to resume duty for almost the whole of his period of service. The accident was rare. M. Epaulard has found in medical literature eight similar cases all terminating in recovery.

Physiological and Therapeutical Action of the Resin of Euphorbium.

The resin of euphorbium finely emulsified and injected into the tissues in very minute doses possesses the remarkable property of producing local æmæmia (*ischémie de la circulation rouge*). M. Périeres has suggested that this action might be used for the checking of hæmorrhage due to uterine fibroids, a condition which often requires surgical treatment. In all the cases of fibroma of the uterus which he has observed he has made use of this resin injected into the cervix, with the result that not only was the hæmorrhage stopped but the fibrous body itself underwent an arrest of development and tended to disappear by continuous regression. M. Périeres read a paper on this subject at a meeting of the Academy of Sciences held on Dec. 24th, 1906.

French Colonial Sickness Statistics.

At the meeting of the Academy of Medicine held on Jan. 15th M. Kermorgan gave an account of the various endemic, epidemic, and contagious diseases prevalent throughout the French colonies in 1905. They can be divided into two distinct categories—namely, those diseases common to both the tropics and to our own temperate regions and those which are distinctly tropical. In the first category come whooping-cough, typhoid fever, influenza, cerebro-spinal meningitis, mumps, measles, tuberculosis, small-pox, and chicken-pox. Of all these tuberculosis merits special attention, for it is mentioned in all the colonial reports as spreading more and more amongst the native populations. Among the maladies special to the tropics must first be mentioned beri-beri, which occupies an important place among the diseases of the natives; cholera, which has prevailed in India and in Indo-China; diarrhoea and dysentery, with or without suppurative hepatitis; leprosy; sleeping sickness, which is much more prevalent than is generally supposed in French West Africa; plague, which is prevalent in India, Cochín China, New Caledonia, and the territory of Quang-Tcheou-Wan; and malaria. This last disease is become much less common in Senegal since the promotion of hygienic measures and the undertaking of regular measures of destruction of mosquitoes and their larvae.

Iodine in the Treatment of Malignant Pustule.

M. André F.-Llobet has for many years insisted upon the excellent results which are obtained by the internal use of iodine in the treatment of malignant pustule. M. Roux read a note on the matter on his behalf before the Academy of Sciences at the meeting held on Jan. 7th. Of 70 cases treated in this way by M. André F.-Llobet, whether in his private clinic or in hospital, since 1891 not one died. Experiments on rabbits, animals very susceptible to anthrax poisoning, have confirmed the curative action of iodine administered by the mouth in this disease. Its value given by injections around the pustular focus is well known but its action as administered by the mouth is less widely recognised.

The Responsibility of an Epileptic Murderer.

PUBLIC opinion in Germany is at present somewhat excited over what is known as the Tessenow case, in which a man has been twice tried at Greifswald, in Pomerania, on a charge of murder, and each time the verdict of the jury was at variance with the unanimous opinion of medical experts.

made. The changes on the Board of Curators of Patronage made during the year were the substitution of Sir William Turner as representing the University Court in place of Sir Patrick Heron Watson, and of Lord Provost Gibson and Bailie Dobie as the representatives from the town council.

University Preliminary Examinations in Scotland.

In the medical preliminary examinations for the Scottish universities the number of candidates and the number of failures are as follows: In the University of St. Andrews, 21, of whom 9 passed in all subjects, 2 in two, and 3 in one, and 7 failed in all; in the University of Glasgow, 107, of whom 30 passed in all subjects, 4 in three, 11 in two, 29 in one, and 33 failed in all; in the University of Aberdeen, 31, of whom 10 passed in all subjects, 4 in two, 3 in one, and 9 failed in all; and in the University of Edinburgh, 147, of whom 51 passed in all subjects, 2 in three, 19 in two, 43 in one, and 32 failed in all.

The Lord Rector's Address at the University of Edinburgh.

The Right Hon. R. B. Haldane, the Lord Rector of the University of Edinburgh, delivered the rectorial address in the M'Ewan Hall on Jan. 10th. The address, it is hardly necessary to state, was of a very high order and all interested in university life and work will find it well worthy of perusal. It is gratifying to be able to state that the students conducted themselves with the utmost decorum. There was a torch light procession at night.

A Well earned Compliment to Dr. W. Bruce.

The members of the Scottish Branch Council who had been associated with Dr. Bruce in the General Medical Council entertained their old colleague at dinner on Jan. 12th, at the North British Hotel, Edinburgh. Sir William Turner, K.O.B., who occupied the chair, proposed Dr. Bruce's health, congratulating him on the good work which he had done in the Council and expressing the high estimation in which he was held. Dr. Bruce replied in feeling terms.

Royal Medical Society.

This society met on Jan. 11th, Dr. N. S. Carmichael being in the president's chair. A dissertation on the Modern Treatment of Fractures by Dr. Wells was read, in the absence of the author, by Dr. J. Gilmour. Dr. W. O. Schlater, B.Sc., read notes of a case of Hemiplegia, and a discussion followed.

Waste of Infant Life in Glasgow.

In its attempt to deal with the problem of reducing its large infantile mortality Glasgow is in at least one respect following the example set by Huddersfield. In one of the most densely populated parts of the city there have just been posted handbills stating that with a view to assist in the reduction of the infant mortality in that district the committee of the Anderston and District Health Association hereby makes offer of a gift of £1 sterling to the mother of each child born between Jan. 1st and June 30th, 1907, provided that the child survives the first year of birth.

Death of Principal Story.

To those who take an interest in the advancement of the cause of education in our Scottish universities the announcement this week of the death of the Rev. Principal Story of Glasgow University must have caused considerable regret. Since 1898 he had held the high office of Principal with much honour to himself and signal advantage to the University. Although previously to his appointment to this position he occupied a chair in the theological faculty, yet it is probably the faculties of medicine and science which have benefited most under his rule. It is true that many factors were at work in bringing this about, yet there is no doubt that the development in these faculties would have been much hampered had it not been for Principal Story's clear comprehension of the ever-increasing demands of the age for fresh equipment and new methods in teaching scientific subjects. He entered upon his duties as Principal at a time of transition and immediately with characteristic energy he set to work and in a short time collected by public subscription a sum of about £100,000 for the purpose of adding to the resources of the University. The handsome buildings, class-rooms, and laboratories for the students of natural philosophy, physiology, materia medica, and medical jurisprudence which have just been erected are the result. It was also, of course, during Principal Story's tenure of office that Mr. Carnegie came

forward with his generous gift to the Scottish University and of this Glasgow received a share. At the moment there is no doubt that in his administrative Principal Story did much for the University, but much by his foresight and business ability he acted in this respect only time will show.

Matriculated Students at the Universities of Glasgow and Edinburgh.

A statement has just been issued giving the number of the matriculated students in the different faculties of the Universities of Glasgow and Edinburgh for the year 1906 and along with it is published for reference the corresponding figures for the last 18 years. In almost every faculty with the exception of that of science, which was started till the year 1893, there is a marked falling of numbers. As regards medicine, in the University of Glasgow for the year 1906 there were 626 matriculated students, as compared with 645 in 1905 and 818 in 1889. This means a decrease of 192 in 18 years. In the University of Edinburgh the matriculated students in 1906 numbered 1465, as compared with 1476 in 1905 and 2025 in the year 1889. This shows a fall of 560 to the extent of 560 in the past 18 years. What the reason of this decrease is it is a little difficult to understand. One would naturally have expected that the institution of the Carnegie scheme for the students would have increased considerably in the years, but apart from economic conditions on the part of the University this has probably been counterbalanced by the raising of the class fees and the higher standard of entrance demanded for the entrance and other examinations.

Grants by Glasgow Corporation for Medical Objects.

The special subcommittee of the finance committee of Glasgow corporation, which was appointed to deal with various applications for grants from the "Common Fund," has decided to make, amongst others, the following recommendations: (1) that a contribution of £3000 in three equal yearly instalments, be granted to the Glasgow Hospital for Sick Children towards the cost of proposed new hospital on the understanding that the committee will choose a site satisfactory to the finance committee of the corporation; (2) that a contribution of £1500 in three equal annual instalments, be granted to the Glasgow Cancer Hospital towards the cost of the proposed extension of the hospital and research department; (3) that a contribution of £900, payable in three equal annual instalments, be made to the funds of Anderson's College Medical School; and (4) that a donation of £50 be made to the fund of the National Society for the Prevention of Cruelty to Children.

(FROM OUR OWN CORRESPONDENTS.)

Health of Dublin.

THE deaths registered in the week ending Jan. 12th equal to an annual death-rate of 31.5 per 1000, as reported in THE LANCET. The average for the year amounted to 26.4 per 1000. This is a melancholy thing in the absence of any special epidemic. The superintendent of Cork-street Fever Hospital reported on Jan. 10th that the admissions there were comprised of cases of measles and scarlet fever with diphtheria, while the number of enteric fever patients had fallen. The main drainage system has now been in operation some months but, as was anticipated, it does not seem to have the least influence in lowering the fatality of the Dublin registration area. It was reported that a severe epidemic of scarlet fever had broken out in the Kingstown township, but the statement has been authoritatively disproved. The members of the corporation are doing whatever they can to maintain the health of the district. On Jan. 14th a new refuse destructor, which cost £5000, was formally handed over to the Corporation by the Horsfall Destructor Co., of London and is now in use.

Epidemics of Typhoid Fever.

For some time there has been a serious outbreak of typhoid fever in the neighbourhood of Jordantown, on the western side of Dublin.

of Belfast Lough, due, it is said, to contagion by milk, while at Holywood, on the opposite side of the same lough, there is also an outbreak, which has been shown to depend on permeation of the surface soil in the affected areas with sewage matter due to defective joints in the sewers.

Citizens' Sunday in Belfast.

In Belfast on Jan. 13th special services were held in the various churches urging the importance of the citizens taking a more active part in the management of civic affairs. The rector of St. George's Church (Rev. Dr. H. D. (FROM OUR OWN CORRESPONDENT.)

The Responsibility of an Epileptic Murderer.

PUBLIC opinion in Germany is at present somewhat excited over what is known as the Tessnow case, in which a man has been twice tried at Greifswald, in Pomerania, on a charge of murder, and each time the verdict of the jury was at variance with the unanimous opinion of medical experts.

The prisoner was a young man, a carpenter, and he had murdered four children on the high road and mutilated the bodies. When the alarm was raised he was found quietly walking along, his clothes and hands bespattered with blood, and he was accordingly arrested. In the prison his behaviour was that of a good-natured person, rather dreamy and quiet, but from time to time he became violent, showed signs of mental confusion and apparently took no notice of his surroundings. He did not seem to realise that he had committed several murders and his memory was a blank as far as the period corresponding to the perpetration of the crime was concerned. At the first trial, which took place about two years ago, the evidence of the medical experts was to the effect that the man's father was an inebriate, that he himself was obviously an epileptic, and that he had committed the crime in a state of epileptic trance. This latter opinion was remarkably confirmed by the prisoner's behaviour after the crime, as he made no attempt to conceal the traces of the murder by washing his hands and clothes. His counsel put in a plea of not guilty because of mental aberration, but the Public Prosecutor insisted that he was responsible for his actions and that the murder was a manifestation of sadism. The jury accepted this view and the man was sentenced to death. On the morning when the execution was to take place he had a typical severe epileptic fit which was followed by complete unconsciousness of long duration. The execution was accordingly postponed and by order of the court the man was placed in a lunatic asylum in order that he might be under observation. A fortnight ago he was brought before another jury; all the medical experts, those who had seen him both in the asylum and in the prison and also the so-called "scientific deputation," which is the highest medical authority in judicial matters, declared once more that the man was an epileptic and that the murder was an unconscious act for which he could not be held criminally responsible. Nevertheless he was again sentenced to death and if the Crown does not exercise its prerogative of mercy he will forfeit his life on the scaffold. The newspapers and medical journals especially blame the second jury for not accepting the well-founded opinions of the medical experts. They call the verdict a legal murder and ask for such an amendment of the law that obviously insane criminals may not be made responsible for their acts. The Tessnow case is not the only one of that kind. When a prisoner is charged with a heinous offence juries are seldom inclined to acquit him, even when mental derangement is proved by the medical evidence. They fear that he may escape from the asylum and that when at liberty he may again commit similar crimes. Moreover, they believe themselves to be as well able to form an estimate of a prisoner's mental state as a medical man is. The excitement caused by the Tessnow case will probably act as a warning to other juries against an obstinate disregard of medical opinions.

A Proposed University at Frankfurt.

It is reported that in Frankfurt there is a well-supported movement which aims at establishing a university in that great and wealthy city. Rich citizens are said to have collected funds for the purpose, but since the creation of universities belongs exclusively to the State and not, as in America, to private initiative the funds will be given to the Government if it approves of the objects of the contributors. It is to be hoped that the project will be carried out, especially in the interests of medical study. Frankfurt has for a long time possessed the nucleus of a medical faculty; the old Senckenberg Institute, founded by a wealthy citizen, contains a number of well-furnished chemical, physical, anatomical, and other laboratories; the Royal Institution for Experimental Therapy under the direction of the celebrated *savant* Professor Ehrlich attracts every year a great many graduates from other parts of Germany and from abroad; the hospitals of Frankfurt are of the first rank and contain an immense amount of clinical material which has not hitherto been used for teaching purposes. The establishment of a university will therefore be easy, so far as the medical faculty is concerned. It is remarkable that the great commercial cities are inclined to extend their educational institutions by the creation of universities, for a similar tendency exists in Hamburg. These tendencies should be supported by the medical profession, as it is in their interest when the scientific institutions and the hospitals of the great cities are made accessible to students. This is all the more the case,

as the clinics of the universities in the small towns often suffer from the want of patients who now find their way in increasing numbers to the great cities for the purpose of obtaining the advice of the celebrated specialists there. No new universities have been founded in Germany for about a century except at Strasburg where the old university existing previously to the French occupation was re-established in 1872.

Death of Dr. Möbius.

Dr. Möbius, who died recently in Leipzig at the age of 53 years, was a well known specialist for nervous disease and one of the most energetic opponents of the so-called emancipation of women. In his sensational work entitled "The Physiological Dementia of Women" he endeavoured to prove that the mental capacity of normal women was decidedly inferior to that of men. A great sensation was also caused by his critical analyses—from the psychiatric point of view—of the characters of celebrated poets and philosophers, such as Rousseau, Nietzsche, Schopenhauer, and others. He had further published a great number of memoirs on hysteria, electro-therapy, and other subjects, and had promoted a movement for the establishment of sanatoriums for nervous patients of the poorer classes.

Jan. 14th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Alleged Leprosy at Bendigo.

A OHINAMAN at Bendigo was alleged by his countrymen to be suffering from leprosy. A careful investigation was made by the local health officer and by Dr. Robertson, medical inspector of the Board of Public Health. The latter reported that the condition, although suspicious, was not leprosy and bacteriological examination had failed to discover any bacilli.

Medical and Dental Practitioners' Bills.

The Bill to amend the Medical Practitioners Act of Victoria passed the Legislative Assembly on Dec. 5th, 1906, with some minor amendments—that the power of the Board to refuse registration to any person convicted of an offence which under the law of Victoria would be a misdemeanour should be subject to approval by the Governor in Council and that medical officers in the army and navy and those who had filled such positions should be registrable. The main provisions of the Bill have been previously outlined; the chief one is the requirement of a five years' course of medical study.—The Bill introduced into the Legislative Assembly of New South Wales by Dr. R. Arthur to provide for reciprocity has made no progress, owing to the opposition of Labour Members. Dr. Arthur said that he was prepared to make some concessions and take the question out of the hands of the Medical Board and place it in those of the Governor in Council. He was willing also to exempt men of high scientific attainments. Dr. Arthur was equally unfortunate with another Bill for amending the Dentists' Act, of which he moved the second reading on Nov. 20th, 1906. In doing so he said that the main objects of the Bill were to fix a standard of examination, especially in preliminary education to give the Dental Board certain powers which the Act was supposed to confer, but did not, in the direction of removing from the Register persons who had made false statements to their qualifications; and to prevent registered men employing unregistered individuals in branch establishments. The Bill was opposed and no progress had been made when time for private Members' business expired.

Hospital Affairs.

The annual meeting of the friends and supporters of St. Vincent's Hospital, Melbourne, was held on Dec. 31, 1906. His Excellency the Governor of Victoria presided and the town-hall was packed with a most enthusiastic audience. The report of the Government Inspector of Charities stated that the building was the most up-to-date hospital in the State and an object-lesson in hospital construction. The cost per bed was £54 8s. 9d., compared with the mean cost of general hospitals of £57 17s. 3d. The proportion of cost of administration to expenditure on maintenance was 2 per cent. During the year 365 male and 463 female in-patients had been treated. The number

of operations performed was 1279, with a death percentage of 2.11. The Premier, in seconding the report, said that he proposed to set aside £20,000 for the next five years towards extending or improving the accommodation of hospitals, on condition that the public contributed £s. for every £s. given by the Government.—On Nov. 23rd, 1906, a conference was held at the town-hall, Melbourne, between representatives of various hospitals in Victoria and of the Royal Victorian Trained Nurses' Association. The first question discussed was the training of nurses in infectious diseases. It was decided that the council of the Royal Victorian Trained Nurses' Association should determine the practical requirements and hold an examination, but that no extension of the present curriculum should be made, in the case of any hospital which was recognised as able to provide the necessary experience. The next matter considered was how to secure efficiency of training in small hospitals. The Royal Victorian Trained Nurses' Association has undertaken with the Australian Trained Nurses' Association not to recognise training in hospitals with less than 10 daily occupied beds, beginning from January, 1907. The Royal Victorian Trained Nurses' Association also proposed that in the case of hospitals with between 10 and 40 beds the larger hospitals should take a proportion of their probationers for the last year of their curriculum. The representatives of the small country hospitals objected to these proposals. They could not afford to pay fully trained qualified nurses. It was suggested that probationers in such hospitals should be allowed if after three years' course there they spent six months at the Women's Hospital, Melbourne, and three months at the Infectious Diseases Hospital before getting a certificate. The conference decided to leave the matter to the hospitals concerned, the council of the Royal Victorian Trained Nurses' Association agreeing to accept such a solution of the difficulty if arrangements could be made. The question of modifying the training in hospitals of from 10 to 40 beds was also left to the hospitals concerned to evolve a scheme by which the larger could assist the smaller ones.—A Bill to provide for the regulation and inspection of private hospitals was introduced into the Legislative Council of New South Wales on Nov. 22nd, 1906, by Dr. Mackellar. He stated that there were in the metropolitan district 107 and in the country 343 establishments which would come within the scope of the Bill. While some were excellent, many were entirely unfit for the purpose. The Bill provided that private hospitals must be licensed by the Minister, on the recommendation of the Board of Health. A special clause dealt with lying-in homes. Sir Arthur Kenrick, M.D., said that a Bill of this description ought to have been introduced by the Government years ago. The Bill was referred to a Select Committee for report.

Friendly Societies.

The annual report of the Registrar of Friendly Societies for New South Wales for 1905, shows that there were 101,463 members of all the societies, and there were 18,248 persons sick for an aggregate term of 104,269 weeks, with a total cost in sick pay of £23,375. An amount of £87,465 was paid for medical attendance and medicine or an average cost of 17s. 6d. per head of mean membership.—A meeting of representatives of the friendly societies in the eastern suburbs of Sydney was held on Nov. 23rd, 1906, to discuss a draft agreement for lodge surgeons drawn up by the New South Wales branch of the British Medical Association. The following motion was carried unanimously:—

That the representatives of the various friendly societies in the eastern suburbs, agree to advise our respective societies that no agreement be entered into with medical officers which contain the following provisions:—(1) To charge a candidate or the lodge for such candidate's examination; (2) making a member receiving £200 per annum ineligible for medical benefits; (3) medicines, &c., to be supplied by medical officers (in lieu of by the chemists as at present).

In the course of the discussion it was seriously proposed that medical institutes should be formed and medical men appointed to them from outside the State.

Inspection of School Children.

The Tasmanian Government has approved of the scheme submitted by the Director of Education for a complete medical examination of all State schools. Local medical men will be appointed at Hobart and Launceston to inspect the scholars and advise teachers, and a woman medical practitioner will be engaged as a permanent member of the education staff to visit all schools where local professional services are not available.—At a recent meeting of the New

South Wales Dental Association a paper was read on the result of inspections by dentists of the teeth of school children. 3156 children and 73,708 teeth were examined. Over 16 per cent. of the permanent and 24.47 per cent. of the temporary teeth were carious. 94 per cent. of the children had decayed teeth. The half-bred Chinese children showed by far the best dentures.

Pure Milk Supply.

The members of the Melbourne Medical Association recently visited the country establishments of a company supplying pure milk and were very pleased with the methods adopted. The cows are all inspected by veterinary surgeons and pronounced free from disease. The milking sheds were properly constructed and the milkers were clean, with washed hands. The milk is cooled to 62°F. at the milking sheds and then cooled to 34° at the railway depot and put into special cooled trucks which keep it at 40° all the way to the town depot where it is pasteurised and put into sterilised bottles in which it is delivered. The company claims to have overcome most of the difficulties, especially great in the heat of summer, incidental to a pure milk supply.

Patent Medicines.

It has been stated in the press here that a meeting in London of the leading makers of proprietary and patent medicines passed a resolution declaring that the publication of trade secrets as provided in the Commonwealth Commerce Act would render trade with Australia impossible. Section 16 of the Commerce Act provides that trade secrets need not be disclosed unless in the opinion of the Governor in Council the disclosure is necessary for the protection of health. In an official handbook on the working of the Act issued last May the following explanatory footnote is attached to the section:—

The object of this section is to prevent the proprietors of trade secrets from losing the benefit of such by their being divulged in the trade description. Where, however, the article, such as a patent medicine, contains anything of a kind which may be injurious if taken without due precaution, such as opium, for example, the regulation may require the fact to be stated on the trade description.

Mineral Springs.

A number of medical men recently visited some mineral springs at Frankton, Victoria, which have been acquired by a company which proposes to erect a sanatorium and medicinal baths. One spring contains iron, brine, and potash and another is a sulphur spring.

Obituary.

Mr. J. A. Sutherland, of Moonee Ponds, a suburb of Melbourne, died on Nov. 18th, 1906, after a brief illness from influenza pneumonia. He had practised in the district for 18 years and was an exceedingly popular as well as a very capable and up-to-date practitioner. He was born in Wick, Scotland, and qualified at the Royal Colleges of Physicians and Surgeons, Edinburgh. He practised in Australia for 36 years. He has one son in the profession who was on his way back to Australia after a visit to England.

Dec. 10th, 1906.

Obituary.

ROBERT TRAVERS LEWIS, B.A., M.B., B.CH. DUB.

THE death of Dr. Robert Travers Lewis from acute pneumonia following upon a chill caught while watching a football match between the University of Cambridge and the West of Scotland occurred on Dec. 2nd, 1906. The fourth son of the late Mr. J. M. Aylward Lewis, J.P., of Ballinacary, county Galway, Dr. Lewis was born in 1859. He was educated at the Runda and at Trinity College, Dublin, where he graduated M.B. in 1885 receiving the degree of B.Ch. in the following year. After practising for a few years in Ireland he went to Willingham, Cambridge-shire, where he soon actively interested himself in the life of that place and rapidly won the esteem of its inhabitants. He held the office of medical officer and public vaccinator of the Willingham district of the Chesterton union and was the only medical man in the immediate vicinity of the village. Till within the last three years he was a member of the parish council and served on the technical education committee. For several years he was president of the public hall, a director of the building society, and was medical officer to the Star Benefit Friendly

Society, the Junior Working Men's Club, and the Hearts of Oak Benefit Society. He also took an active interest in the temperance question, being president of the Undenominational Temperance Society. He was not only an enthusiast in local sports himself but succeeded in engendering his enthusiasm among the people of the village, where hockey, cricket, and lawn tennis received a large share of attention. The deceased has left a widow and family.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the first professional examination of the Conjoint Examining Board just completed the following gentlemen were approved in the subjects indicated:—

Chemistry and Physics.—Percy Lytton Tempest Bennett, London Hospital; Harold James Dorsetford-Hoelias, Technical School, Plymouth; Henry George Barham Blackman, Guy's Hospital; William Houston Boyd, Queen's College, Belfast; Stacey Archer Burn, St. Bartholomew's Hospital; Carol Adolph Kaufman, Birkbeck College; Reginald Charles Clifford, Polytechnic Institute; Eric Clarence Oline, Guy's Hospital; Herbert Edward Cockcroft, Manchester; Charles Frederick Constant, Guy's Hospital; Leonard Marshall Crockett, Charing Cross Hospital; André Constant Labauve, d'Arlet, Guy's Hospital; Henry Harvard Davis, Guy's Hospital; William Everard Sherard Digby, Guy's Hospital; Paul Dvorkowitz, St. Bartholomew's Hospital; George James Frank Elphick, St. Mary's Hospital; Montague Albert Farr, Charing Cross Hospital; Claude Emory Freeman, Sheffield University; Andrew Alexander Fyffe, Sheffield University; David Harvard, University College, Cardiff; Arthur Stanley Heale, New Zealand University and London Hospital; Cecil Norman Hutt, St. Bartholomew's Hospital; William Sadler Hyde, Guy's Hospital; Griffith Lewis Jones, University College, Cardiff; Donald Aldridge Macpherson, Charing Cross Hospital; Dalton Mallam, London Hospital; Avenol Frederick Cleave Martyn, St. Mary's Hospital; Owen David Baker Maxson, London Hospital; Henry Locke Paddon, B.A. Oxon.; St. Thomas's Hospital; John Lansdowne Percival, Guy's Hospital; Alfred Spearman Fern, St. Thomas's Hospital; Richard Goodenough Rice, London Hospital; George FitzPatrick Riden, King's College; Harold Robinson, Victoria University, Manchester; Lawrence Lancaster Satow, St. Bartholomew's Hospital; Thomas Stoney Sharpley, Guy's Hospital; Henry Lionel Hughes Steele, St. Thomas's Hospital; Frederick Tooth, Sydney University; Harry Alfred Turner, Science and Art Institute, Walsall; Frank Wells, St. Mary's Hospital; Arthur Tudor Williams, London Hospital.

Biology.—Charles Vernon Anderson, St. Thomas's Hospital; John Claude Beckett, St. Mary's Hospital; Norman Stuart Carruthers, Guy's Hospital; Cyril James Weston Clayton, St. Mary's Hospital; Charles Frederick Constant, Guy's Hospital; Hugh Grogan Crawford, Guy's Hospital; Henry Harvard Davis, Guy's Hospital; Hubert Daw, Guy's Hospital; John Dotto, St. Bartholomew's Hospital; Christopher Robson Dudgeon, Westminster Hospital; Daniel Charles Evans, University College, Cardiff; John Kenneth Garner, Liverpool University; William George Healey, South-Western Polytechnic; Hugh Granville Hockridge, St. Bartholomew's Hospital; Gordon Alexander Hodgson, Leeds University; Darrell Robert Norman O'Neale Humphrey-Dav, St. Mary's Hospital; Allan Wellesley Lewis, St. Mary's Hospital; Mark Lindsey, St. Bartholomew's Hospital; Eadbert Ralph Longstaff, St. Bartholomew's Hospital; Edward Mills Marshall, King's College; John Lansdowne Percival, Guy's Hospital; John Arnoux Prendergast, Leeds University; Christopher Hugh Leete Rixon, St. Thomas's Hospital; Thomas Stoney Sharpley, Guy's Hospital; George Holmes Smith, L.D.S., Birkbeck College; Frederick Tooth, Sydney University; Charles Rustace Williams, Birkbeck College; and Owen Elias Williams, Guy's Hospital.

The following gentlemen passed the second professional examination held on Jan. 3rd, 4th, 7th, and 8th:—

Anatomy and Physiology.—Guy Oldham Chambers, St. Bartholomew's Hospital; John Joseph Clarke, London Hospital; William Thomas Clarke, Guy's Hospital; Henry Gray Woodhouse Dawson, Sheffield University; Hensell How and Dunmore, London Hospital; Frederick Dunphy, Westminster Hospital; Edwin Charles East, Birmingham University; Alfred James Graves, Columbia University, New York; and Charing Cross Hospital; Geoffrey Richard Heard, London Hospital; Gilbert Percy Humphry, King's College and St. George's Hospital; Roger Percival Jones, University College, Cardiff; and University College Hospital; Fritz Kalkenberg, Glasgow University and Guy's Hospital; James Arthur Richard Lee, Sheffield University; Charles Eric Lowe, Westminster Hospital; Alexander Ernest McKenzie, Victoria University, Manchester; John Charles Mackwood, London Hospital; John Mitchell McHaffey, New Zealand and London Hospital; Douglas Ashley Mitchell, Guy's Hospital; Leonard William Mortimer, London Hospital; Humphrey Nemo, London Hospital; Richard Alfred Parsons, St. Mary's Hospital; Richard Blidolph Phillips, University College Hospital; Edward Holmes Ratnor, London Hospital; Harold Thaxter, Birmingham University; Francis Christopher Tibbs, London Hospital; George Ernest Villandro, London Hospital; John Glegg Watson, London Hospital; Charles Fitzgerald de Wiles, St. Bartholomew's Hospital; Sydney Williams, University College, Cardiff; Charles Stewart Wink, St. Thomas's Hospital; Duncan Wood, London Hospital; and Charles Reynolds Woodruff, St. Bartholomew's Hospital.

At the quarterly examination in Practical Pharmacy of the Conjoint Examining Board the following gentlemen were approved:—

Edward Morrison Adam, Charing Cross Hospital; Isaac Barnett Bernstein, Leeds University; Harry Barrett Corry, B.A. Cantab., London Hospital; Gustavus William Musgrave Cusance, St. Thomas's Hospital; Benjamin Dale, St. George's Hospital; Thomas Ronald Davey, St. Mary's Hospital and private; Archibald Davidson, Guy's Hospital; Evan Richard Evans, St. Bartholomew's Hospital; Alexander Savill Graham, Charing Cross Hospital; Thomas Arthur Jones, B.A. Cantab., Cambridge University and London Hospital; James Leonard Joyce, Cambridge University and St. Bartholomew's Hospital; Ernest Albert Saunders King's College Hospital; John Richard Cook Stephens, London Hospital and private; Gilbert Francis Syms, Guy's Hospital; and Gerald Douglas Hamilton Wallace, Charing Cross Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—In the Preliminary Science Examination for the Licence in Dental Surgery the following gentlemen were approved in the subjects of Chemistry and Physics:—

Herbert Ferris Barge, Charles Ernest Blows, Ernest Benjamin Brown, and Henry James Burch, Birkbeck College; Norman Sambell Card, Liverpool University; Neville Dutton Clarke, Queen's College, Belfast; and Guy's Hospital; Arthur Josiah Dabbs, Birmingham University; Norman Malcolm McArthur Douglas, Liverpool University; George Vivian Dymott, Birkbeck College; Ernest William Frank Falkner, Municipal School, Grimsby, and Liverpool University; Frank Leonard Furze, Birkbeck College; Henry Hall, Charing Cross Hospital; Harold Holburn, Sheffield University; Arthur Percy Livett Johnson, Birkbeck College; Charles Ernest McNabb, Technical Institute, Salford, and Municipal School, Manchester; Frederick Edward Marston, Wiggleson School, Leicester; Charles Harry Greville Penny, Polytechnic Institute, George Orchard Roper, Royal Albert Memorial College, Exeter, Alfred Edmund Victor Spill, University College, Cardiff, Carl Stacey, Polytechnic Institute; Joseph Magnus Watson, Rutherford College; and George Kerry Wild, Birmingham University.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examinations held recently the following candidates passed in the subjects indicated:—

PART I.

Biology.—I. M. Bernard, Royal Free Hospital; and H. Cox, Birmingham.

Chemistry.—R. G. Cassell, London Hospital.

Matéria Medica.—R. U. Carey, London Hospital; B. M. Malden, Royal Free Hospital; and V. P. Norman, London Hospital.

PART II.

Anatomy.—N. B. Benjafield, University College Hospital; M. Bennett, Royal Free Hospital; J. Bramley-Moore, University College Hospital; H. S. Brown, Birmingham; G. G. Rigby, Manchester; and W. H. Watson, Guy's Hospital.

Physiology.—N. B. Benjafield, University College Hospital; M. Bennett, Royal Free Hospital; J. Bramley-Moore, University College Hospital; H. S. Brown, Birmingham; C. S. Foster, Westminster Hospital; M. Graves and V. P. Norman, London Hospital; G. G. Rigby, Manchester; S. H. Scott, London Hospital; and W. H. Watson, Guy's Hospital.

UNIVERSITY OF CAMBRIDGE.—The following having passed the required examinations are entitled to the University Diploma in Tropical Medicine and Hygiene:—

S. L. Cummins, A. Fenton, S. A. Harris, A. E. Horn, H. B. G. Newham, W. G. B. Orme, J. D. Smith, and F. M. Suckling.

A University Lectureship in Hygiene, with an annual stipend of £100, was established by grace of the Senate on Jan. 17th. Dr. D. MacAlister has been appointed a member of the syndicate for the institution of a Diploma in Architecture.

BIRMINGHAM HOUSING COMMITTEE AND THE BORDLESLEY-GREEN SCHEME.—The housing committee does much good work and ably seconds the medical officer of the city. During the past five years it has rendered 1157 houses habitable, has closed 913 which were unfit for habitation, and has demolished 519. It has been sympathetic towards all schemes for land purchase and town planning, and in pursuance of the policy of municipal purchase it acquired some time ago a piece of land at Bordesley, the idea being that the land should be let on leases to be utilised for the erection of workmen's dwellings. There has been difficulty in disposing of the land on proper terms, and the committee now proposes to lease it to the Ideal Benefit Society which desires to erect upon it, and on an immediately adjacent piece of ground, dwellings suitable for its members who belong to the better class of artisans. According to the scheme of the housing committee the land is to be leased to the society for 109 years, the usual leasehold time being exceeded in order that the society may grant a full 99 years' lease to any of its members who may purchase at any time in the first ten years of the society's tenure, within which period the land must be fully developed. Under the scheme the city will begin to make a definite and not unreasonable profit at the end of 22 years.

Before the scheme can be carried out the approval of the Local Government Board will have to be obtained and serious opposition is threatened by the committee of the Birmingham Trades' Council, which holds that the land was not intended for the erection of the class of houses now proposed, but for houses adapted to the means of the lower classes of workmen who earn about £1 per week. The matter was argued somewhat hotly at a recent meeting of the trades' council and artisans who could afford houses of the character contemplated under the new scheme were stigmatised as aristocratic.

VITAL STATISTICS IN RUSSIA.—In a statement which has been just issued on public health in Russia in 1904 it is shown that in European Russia the mortality was 29.1 per 1000. Although in comparison with the death rates in other European countries this is very high, it is very low compared with the average for the preceding 15 years in Russia. The birth-rate for the year was 47.3 per 1000, so that the natural increase of the population was 18.2 per 1000, which is higher than for any of the preceding 15 years. The *Pharmaz Journal* points out that owing to the number of reserves called to the war the number of civilian medical men in practice at the end of the year under review was 16,144, as compared with 17,656 at the end of the preceding year. The total number of patients treated at the hospitals was 2,028,031, of whom 112,194 died (5.5 per cent.). 155,000 cases were treated at the maternity hospitals where the mortality was 0.5 per cent.

INFANTS' HOSPITAL, LONDON.—The Duchess of Albany has agreed to be the first patron of the new Hospital for Infants now in course of erection at Vincent-square, Westminster, S.W. This hospital was established in temporary premises in Hampstead early in 1903 and the great success achieved by the treatment of infants suffering from malnutrition has led a member of the committee to erect the new hospital entirely at his own expense, the work of maintenance being all that the public and friends of the hospital are asked to provide. The new building will contain 50 cots and accommodation for the nursing staff, and the committee earnestly pleads for help. The constitution, by laws, and regulations of the hospital provide that donors of 50 guineas shall be entitled to all the privileges of life governors, and annual subscribers of 1 guinea shall be governors of the hospital during the continuance of such subscription and as such shall be the authority which annually appoints the committee of management. Detailed information concerning the hospital will be gladly given by the secretary at the temporary office of the Infants' Hospital, 120, Victoria-street, London, S.W., or by the matron at the present hospital at Hampstead.

UNIVERSITY COLLEGE, LONDON.—The annual report of the council of University College has just been issued. The number of students in the college for the session 1905-06 was 1396, of whom 242 belonged to the Faculty of Medicine and 134 were post graduate and research students. There were 468 internal students of the University of London—that is, students taking full courses for degrees at the University of London. There were besides about 800 persons attending "public" and "special" courses. The fees received in all the faculties of the college amounted to £22,823, being an increase of upwards of £2500 on the previous session. The financial statements show that the income exceeded the expenditure by £126, that the Treasury grant amounted to £10,000, and that the general finances of the college are in a healthy condition. The report contains a summary of the research work done during the past session, the researches in the department of chemistry, including those of Sir William Ramsay in respect of neon and helium, being among the most interesting. The report also summarises the steps that have been taken for the union of the college and the University of London. On Jan. 1st of the present year the college ceased to be a school of the University and became incorporated with it, thus realising the aims of those who in 1826 founded it. It is the first college thus to be incorporated with the university, and it is understood that its example will be followed by King's College. Important additions have been made during the past year to the departments of physics and chemistry and a plan has been worked out for the re-arrangement of many of the college departments. This will be possible when the new buildings for the School of Advanced Medical Studies, now in course of erection by the generosity of Sir Donald

Carrie, and when the new buildings of University College School at Hampstead are completed. The new medical school buildings will be completed during the next few months.

WEST AFRICAN MEDICAL STAFF.—The following appointments have been made to the West African Medical Staff:—H. Catling, M.R.C.S. Eng., L.R.C.P. Lond., Southern Nigeria; F. H. Storey, M.B., Ch.B., Univ. Liverp., H. W. Gu-h, M.B., Ch.B. Chin., F. I. M. Jupp, I.S.A., and T. H. Dagon, M.R.C.S. Eng., L.R.C.P. Lond., Gold Coast; and A. B. S. Powell, L.R.C.P. & S. India, L.P.S. Glasc., A. H. Wilson, M.B., Ch.B. Camb., C. C. Robinson, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng., and H. M. Newport, M.R.C.S. Eng., L.R.C.P. Lond., Southern Nigeria. W. R. Henderson, O.M.G., M.D. R.U.I., principal medical officer of the Gold Coast, retires on pension. G. F. Darker, M.R.C.S. Eng., L.R.C.P. Lond., medical officer in Southern Nigeria, and D. Cowin, M.B., B.Ch. Viet Univ., medical officer in the Gold Coast, resign. H. Kramer, M.B., B.Ch. Chin., medical officer in the Gold Coast, is invalided from the service. W. H. G. H. Best, L.R.O.S. & P. Ire., medical officer in Southern Nigeria, is promoted to be senior medical officer, vice G. J. Rutherford, M.R.C.S. Eng., L.R.C.P. Lond., transferred. I. H. Read, M.R.C.S. Eng., L.R.C.P. Lond., medical officer in Southern Nigeria, is promoted to be senior medical officer, vice F. G. Hopkins, M.D. Dub., promoted.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of this society was held on Jan. 9th, Dr. G. F. Mansford, the President, being in the chair. Fifteen directors were present. The deaths of two members were reported and the resignation of one was accepted. Three new members were elected. The deaths of two widows were also reported; one, whose husband had paid a life subscription fee of £26 5s., had received in grants £1217, and the other £857, her husband having paid £21 in subscriptions. £536 had been distributed as a Christmas present amongst the annuitants of the charity. The sum of £1275 10s. was voted for the half-yearly grants to the 43 widows and 21 orphans at present in receipt of grants. During the past quarter six letters had been received from widows of medical men asking for relief, but this had to be refused as their husbands had not been members of the society. An application for relief was received from the widow of a member and a grant at the rate of £40 per annum was made. Membership of the society is open to any registered practitioner residing within a radius of 20 miles from Charing Cross. Full particulars may be obtained from the secretary at 11, Chandos-street, Cavendish-square, London, W.

OPENING OF THE NEW LIVERPOOL INFIRMARY FOR CHILDREN.—Her Royal Highness the Duchess of Albany formally opened the new Infirmary for Children on Jan. 10th. The Lord Mayor of Liverpool presided at the ceremony, which was largely attended and included the Earl of Derby, the Lord Bishop of Liverpool, Lady Isabel Gathorne Hardy, and the Lady Mayoress. The rebuilt infirmary was founded in 1851 by the late Dr. Alfred Stephens of 4, Upper Parliament-street, Liverpool, who was the senior physician to the infirmary for upwards of a quarter of a century. He conceived the idea as the result of a visit to the old children's dispensary in Dublin. The infirmary had its beginning in a small house in Upper Hill-street, the work being then confined to out-patients. In 1856 larger premises were obtained and provision was made for a few in-patients. In 1866 the late Duke of Edinburgh laid the foundation-stone of the building which unfortunately (on the advice of sanitary experts) had to be demolished owing to the frequent outbreaks of diphtheria and scarlet fever. The demolished infirmary provided accommodation for 80 in-patients; the new building will accommodate 100 in-patients, exclusive of six cots in the observation block. The old building also proved inadequate for the treatment of the out-patients and necessitated the building of an out-patient department separate from the main building, which was opened by the Countess of Derby in 1902, a description of which was given in THE LANCET. In 1903 the infirmary was pulled down owing to the frequent outbreaks of infectious diseases mentioned above. The total cost of the buildings, including the purchase of land, was £68,000. The infirmary has been built and equipped with all the most recent improvements and is a very imposing building.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX, 8, Henrietta street, Covent Garden, London, W.C.

Aids to Medical Diagnosis. By Arthur Whitting, M.D., M.R.O.P., Physician to the Tottenham Hospital and Assistant Physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest. Price, paper, 2s.; cloth, 2s. 6d.

CASSELL AND COMPANY, LIMITED, London, Paris, New York, and Melbourne.

Tumours, Innocent and Malignant: their Clinical Characters and Appropriate Treatment. By J. Bland-Sutton, F.R.C.S., Surgeon to, and Member of, the Cancer Investigation Committee of the Middlesex Hospital, &c. Fourth edition. Price 21s.

CHURCHILL, J. AND A., 7, Great Marlborough-street, London, W.

A Handbook of Physics and Chemistry. Adapted to the Requirements of the First Examination of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons and also for General Use. By Herbert E. Corbin, B.Sc. Lond., M.R.C.S., L.R.C.P., D.P.H., Medical Superintendent, London Fever Hospital, and Archibald M. Stewart, B.Sc. Lond., B.A., T.O.D., Headmaster of Alresford Grammar School. Third edition. Price 6s. 6d. net.

F. A. DAVIS COMPANY, 1914-16, Cherry-street, Philadelphia, Pa., U.S.A.

A Practical Treatise on Materia Medica and Therapeutics. With Especial Reference to the Clinical Application of Drugs. By John V. Shoemaker, M.D., LL.D., Professor of Materia Medica, Pharmacology, Therapeutics, and Clinical Medicine, and Clinical Professor of Diseases of the Skin in the Medico-Chirurgical College of Philadelphia. Sixth edition, thoroughly revised. Price 85 net.

- THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Sturminster Newton, in the county of Dorset.

Births, Marriages, and Deaths.

BIRTHS.

- DEANEY.—On Jan. 6th, at Waterloo Road, Wolverhampton, the wife of Edward Deane, M.D., F.R.C.S., of a daughter.
- GILFORD.—On Jan. 2nd, at Oxford Road, Reading, the wife of Sidney Gilford, M.B., Ch.B., of a daughter.
- HEPBURN.—On Jan. 11th, at Pevensey, Enfield, the wife of Malcolm L. Hepburn, M.D., F.R.C.S., of a daughter.

MARRIAGE.

- ANDREWS—FRANCIS.—On Jan. 5th, at St. Mary Abbots, Kensington, Cecil Edward Andrews, M.R.C.S., L.R.C.P., to Zenobia, youngest daughter of the late Major T. J. Francis, 9th and 16th Lancers.

DEATH.

- TAYLER.—On Jan. 6th, at Harford, Kingsdown, Dover, William Henry Tayler, M.D., aged 75 years.

F.B.—A fee of 1s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A FRIEND'S ADVICE.

At a recent inquest held at Scarborough evidence was given that the deceased suffered from quinsy and consulted a friend who was ill-advised enough to recommend him a course which, strange to say, he adopted. The prescription consisted in taking half an ounce of collyer's elixir of potassium borogluconate dissolved in water in the morning and a similar dose at night. Whether these measures were to be continued indefinitely was not stated, for on the day following the consumption of the quantity mentioned, equal to 450 grains of chloride of potassium the patient died. It might be interesting to know by what process the friend who gave the advice arrived at his singular "remedy" and who first suggested that borogluconate which are of more or less popular consumption should be infused in such a manner. It is to be hoped that anyone who has heard of this new domestic "cure for quinsy" and is waiting for an opportunity to try it will read of the inquest mentioned and be warned in time.

NOVOCAINE.

To the Editors of THE LANCET.

SIR,—I should be much obliged if any of your readers would inform me as to the following points in cases of dental extractions: 1. Is novocaine at all superior to eucaine? 2. What amounts of each respectively is it safe to inject in cases requiring many teeth removed? 3. The technique of injecting these fluids so as to insure the greatest amount of anaesthesia possible. I mean as regards insertion of needle, &c. I enclose my card, and remain, Sir, yours faithfully,
Jan. 14th, 1907.
DISTAL.

THE MISLEADING ADVERTISEMENT.

In the issue of Jan. 12th of our contemporary John Bull we find on p. 45 in the "Answers to Correspondents" the following excellent advice: "Avoid the Magic Foot Draught Company and all other quacks." On p. 41, however, we see a flaming advertisement of the British Electric Institute which sells the Ajax Dry Cell batteries. This advertisement, as is usual with electrical quacks, quotes opinions by medical men upon the uses of electricity and, moreover, gives a quotation from the writing of the late Dr. W. E. Stevenson (he has been dead some 15 years) in our columns. From the advertisement it might be inferred that Dr. Stevenson advocates the Ajax Dry Cell in our columns and that we ourselves approve of it too. What we really think about the Ajax Dry Cell may be seen in our issue of June 9th, 1906, p. 1653. But anyway, we think that the editor of John Bull should make his counsel as to avoidance of quacks fit his practice by excluding their advertisements.

THE TREATMENT OF "NEURALGIA."

To the Editors of THE LANCET.

SIR,—Replying to "G."s Inquiry in your issue of Jan. 6th, I would suggest a careful search for "pressure" on the posterior spinal roots of the brachial plexus. The "not very marked tenderness" there is suggestive, and I have seen a case with similar symptoms at once cured by the removal of a small sebaceous cyst. If nothing can be found I would suggest the application of that most excellent weapon, Corrigan's button. I am, Sir, yours faithfully,
Southport, Jan. 14th, 1907.
COLIN CAMPBELL.

DIET IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIR,—Can any of your readers kindly inform me where I can find statistics showing the relative value of the old liquid and the new (more) solid dietaries in typhoid fever?

Jan. 11th, 1907.

I am, Sir, yours faithfully,

GARGANTUA.

MANCHESTER CREMATORIUM.

The annual meeting of the shareholders of the Manchester Crematorium held on Dec. 23rd, 1906, was the seventeenth of the series. The report of the directors seems to show an undercurrent of disappointment with the comparatively slow progress made by cremation in this district. Indeed, it is said to be "unpopular in the North." The report does not rest the claims of cremation for support solely on the hygienic or sanitary aspects of the matter but appeals also to the love of cheapness which is believed to be a very general characteristic of our times. It is stated that the dead can be cremated for much less than they can be buried, if there is taken into consideration "the subsequent expense after interment in the erection of a memorial to the deceased, as against the moderate cost of a niche for the reception of the urn containing the ashes of the deceased." There are, of course, many arguments in favour of cremation but it may rather jar on some minds when the grimly commercial view of the question is put prominently forward.

WELLCOME'S PHOTOGRAPHIC EXPOSURE RECORD AND DIARY.

We have received from Messrs. Burroughs, Wellcome and Co. their photographic diary for 1907. It contains some useful information concerning the practical details of photographic manipulation. The directions given, combined with the simplicity and convenience of the mechanical calculator and tables of light values, should render the estimation of correct exposure a simple matter. The articles on machine development, and on tank or stand development fully describe the manipulations connected with these methods. Each book is accompanied with a folding card showing the timing of development by the factorial method for various degrees of contrast. The book will be found a distinct aid to all interested in practical photography.

PHARMACOLOGY.

We have received from Messrs. Southall Brothers and Barclay of Birmingham a copy of their fifteenth annual laboratory report which contains many interesting observations on pharmacological progress. This report shows amongst other things that a considerable amount of work has been done in regard to the chemical and physiological standardisation of atropine, from which it appears that the different varieties of atropine contain glucosides essentially different not only in their toxic effect but different also in chemical constitution.

Honestas.—The story is not an edifying one. A seems to us to have lost his practice to B in fair competition, but anyone purchasing B's practice would have to remember that B paid nothing for it, so that the title was insecure. With regard to "C" using confidential information obtained from B's wife we do not see that this is proved, nor even that it was necessary for C to obtain confidential information at all to enable him to understand the situation. C's old relations with A make it probable that they acted in unison from the beginning. While we sympathise with D we do not see that anything has been done of which the General Medical Council, the only tribunal which the medical profession possesses, could take notice. The Council, however, might have a different opinion if the facts were submitted to it.

Interested.—We deplore such paragraphs but in our experience the beleaguered medical man is not as a rule the offender. The invidious friend, sometimes acting as a correspondent to, and sometimes actually connected with, a newspaper is almost always the author of such paragraphs. Can our correspondent prove that the medical man in question wrote or inspired the paragraph himself?

Mr. R. K. Contractor.—If our correspondent is correct in his facts his best course is to bring the subject to the notice of the Indian Government authorities in Bombay. It would probably be necessary to prove that the person in question had really made use, or was at the time making use, of the title of Doctor of Medicine by virtue of an authority of the degree mentioned by our correspondent.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (3 P.M.), St. Mark's (2.30 P.M.).

TUESDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M.), Ophthalmic, 2.15 P.M., Tottenham (2.30 P.M.).

WEDNESDAY (23rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Free (2 P.M.), Royal Orthopaedic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.).

THURSDAY (24th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopaedic (3 P.M.), Royal Free (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.), Tottenham (Gynecological, 2.30 P.M.).

FRIDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopaedic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Auril, 2 P.M.), Tottenham (2.30 P.M.).

SATURDAY (26th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (22nd).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (21, Hanover-square, W.).—8.30 P.M.: Papers.—Dr. H. C. Bastian: On the De-novo Origin of Bacteria. Bacilli, Vibrios, Micrococci, Toruli and Moulds in certain previously Superheated Saline Solutions contained within Hermetically Sealed Tubes.—Dr. S. West and Dr. T. W. Clarke: Idiopathic Cyanosis due to Sulph hæmoglobinæmia, (Epilidæic demonstration).

THERAPEUTICAL SOCIETY (Apothecaries' Hall, Blackfriars, E.C.).—4.30 P.M.: Papers.—Dr. R. B. Wild: The Proper Scope of the Teaching of Materia Medica, Pharmacology, and Therapeutics in the Medical Curriculum.—Dr. Bonney: On a New Method of rendering Croscoto and Cannable Indica Soluble, and Short Notes on certain Useful but Little Known Drugs.

WEDNESDAY (23rd).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M.: Hunterian Lectures.—Mr. M. Robson: Points in the Diagnosis and Treatment of Duodenal Ulcer.

FRIDAY (25th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M.: Clinical Evening for the Exhibition of Cases followed by Discussion. Patients in attendance from 8 to 9 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (21st).—MEDICAL GRADUATES' COLLEGE AND POLYTECHNIC (22, Chancery-street, W.C.).—4 P.M.: Dr. W. Fox: Clinique (Skin). 5.15 P.M.: Lecture.—Dr. G. E. Herman: Some Points in Connection with Dysmenorrhœa.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—12 noon: Pathological Demonstration.—Dr. G. C. Low: 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M.: Lecture.—Mr. Bellwin: Practical Surgery.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 A.M.: Clinique—Surgical Out-patient (Mr. B. Evans). 2.20 P.M.: Cliniques: Medical Out-patient (Dr. Whipple), Throat, Nose, and Ear (Mr. Carson); X Ray Demonstration (Dr. Fife).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Sir D. Duckworth: Medicine. 3.15 P.M.: Mr. W. Turner: Surgery. 4 P.M.: Dr. St. Clair Thomson: Diseases of the Throat, Nose, and Ear. Out-patient Demonstrations.—10 A.M.: Surgical, and Medical. 12 noon: Eye and Throat. Special Lecture.—Sir D. Duckworth: Cirrhosis of the Liver.

TUESDAY (22nd).—MEDICAL GRADUATES' COLLEGE AND POLYTECHNIC (22, Chancery-street, W.C.).—4 P.M.: Dr. J. Taylor: Clinique (Medical). 5.15 P.M.: Lecture.—Dr. R. Jones: The Insane Temperament.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moulton: Gynecology. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: X Rays. Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Clinical Lecture.—Mr. Armour.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—10.30 A.M.: Clinique.—Medical Out-patient (Dr. Auld). 2.30 P.M.: Surgical Operations (Mr. Carson); Cliniques: Gynecological Out-patient (Dr. Giles), Surgical Out-patient (Mr. Edmunds). 4.30 P.M.: Lecture.—Dr. Whipple: Erythema in Children.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. R. T. Bewlett: Medicine. 3.15 P.M.: Mr. Carless: Surgery. 4 P.M.: Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queens-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture.—Mr. Sargent: Surgery of the Brachial Plexus.

CHARING CROSS HOSPITAL.—4 P.M.: Demonstration.—Dr. MacLeod: (Dermatological). (Post-Graduate Course.)

WEDNESDAY (23rd).—MEDICAL GRADUATES' COLLEGE AND POLYTECHNIC (22, Chancery-street, W.C.).—4 P.M.: Mr. A. H. Tubby: Clinique (Surgical). 5.15 P.M.: Lecture.—Dr. A. E. Giles: Developments and Disorders of Extra Uterine Gestation.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. Dr. Robinson: Diseases of Women. 5 P.M.: Lecture.—Dr. Beddard: Practical Medicine.

THE EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 P.M.: Clinique.—Dermatological (Dr. Meachen), ophthalmological (Mr. Brooks), Medical Out-patient (Dr. Whipple).
SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. F. Taylor: Clinique. 3.30 P.M.: Mr. Cargill: Ophthalmology. Out-patient demonstrations.—10 A.M.: Surgical and Medical. 11 A.M.: Eye.
GENERAL THROAT AND EAR HOSPITAL (Gray's Inn-road, W.O.).—5 P.M.: Demonstration.—Dr. Abercrombie: Nose and accessory Sinuses.

ESDAY (24th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.O.).—4 P.M.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M.: Lecture.—Mr. L. Mummery: The Special features of Appendicitis in Children.

POST-GRADUATE COLLEGE (West London Hospital, Hammer-smith-road, W.).—2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays, Operations. Mr. Dunn: Diseases of the Eye. 5 P.M.: Clinical Lecture.—Dr. Davis.

THE EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 P.M.: Gynecological Operations (Dr. Giles). Cliniques.—Medical (Dr. Whiting), Surgical Out-patient (Mr. Jackson). 3 P.M.: Clinique.—Medical In-patient (Dr. Chapple). 3.30 P.M.: Lecture.—Dr. Meachen: Demonstration of Selected Skin Cases.

SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. G. Rankin: Medicine. 3.15 P.M.: Sir W. Bennett: Surgery. 4 P.M.: Dr. H. Cooper: Radiography. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat. Special Lecture.—Sir W. Bennett: Concerning Pain in the Groin.

JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.O.).—6 P.M.: Chesterfield Lecture.—Dr. M. Dockrell: Syphilis: Popular (I., Miliary; II., Lenticular; III., Squamous; IV., Molar, Pustular and Tuberculous).

LARING CROSS HOSPITAL.—4 P.M.: Dr. Routh: Demonstration (Gynecological). (Post-Graduate Course.)

HOSPITAL FOR SICK CHILDREN (St. Ormond-street, W.O.).—4 P.M.: Lecture.—Dr. Hutchison: Infant Feeding.

DAY (25th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.O.).—4 P.M.: Mr. S. Stephenson: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammer-smith-road, W.).—10 A.M.: Dr. Moullin: Gynecology. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: X Rays. Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Lecture.—Mr. Lloyd: Anesthetics.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—3.30 A.M.: Clinique.—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds). Cliniques.—Medical Out-patient (Dr. Auld), Ophthalmological (Mr. Brooks). 3 P.M.: Clinique.—Medical In-patient (Dr. Leslie).

SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. R. Bradford: Medicine. 3.15 P.M.: Mr. McGavin: Surgery. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Skin.

NATIONAL HOSPITAL FOR THE PARALYZED AND EPILEPTIC (Queens-square, Bloomsbury, W.O.).—3.30 P.M.: Clinical Lecture.—Sir V. Horsley: Surgery of the Nervous System.

THURSDAY (26th).—POST-GRADUATE COLLEGE (West London Hospital, Hammer-smith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. Dr. Robinson: Diseases of Women.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1906, which was completed with the issue of Dec. 29th, were given in THE LANCET of Jan. 5th, 1907.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1906 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.O., are dealt with by them? Subscriptions paid to London or to local newagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularly in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	... £1 12 6	One Year	... £1 14 8
Six Months	 0 16 3	Six Months	 0 17 4
Three Months	 0 8 2	Three Months	 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.O.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

EDITORIAL NOTICES.

It is most important that communications relating to the editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners. Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

METEOROLOGICAL READINGS.

(Taken daily at 8.50 a.m. by Edward's Instruments.)

A Clinical Lecture

ERYTHEMA NODOSUM AND RHEUMATISM.

Delivered at Bristol General Hospital.

By J. ODERY SYNES, M.D. LOND., D.P.H.,
M.R.C.S. ENG., L.R.C.P. LOND.,ASSISTANT PHYSICIAN AND BACTERIOLOGIST, BRISTOL GENERAL
HOSPITAL.

GENTLEMEN.—The disease (erythema nodosum) which I am bringing to your notice to-day is more commonly seen amongst hospital out-patients than in private practice. Many cases are so slight that the condition is passed over without medical aid being called for, and in severe cases the rash may be so ill-defined, and the constitutional symptoms so severe that the case is wrongly diagnosed as rheumatic fever, enteric fever, or broncho-pneumonia. Two entirely different views are held as to the nature of erythema nodosum. The more widely accepted view is that the condition is rheumatic in origin, like chorea, tonsillitis, endocarditis, and pericarditis, a manifestation or symptom of the rheumatic state. The second view, which is gradually gaining ground at the present time, is that erythema nodosum is an acute infective fever of a definitely specific nature.

I purpose to bring to your notice some of the facts for and against the theory of the rheumatic origin of the disease, and although these facts may not enable you to arrive at any definite conclusion, they cannot fail to stimulate your interest and lead you to pay a closer attention to such cases as you may meet in the future. First let me read an abstract of the notes on a case of erythema nodosum recently in the hospital.

A married woman, aged 50 years, was admitted to the Bristol General Hospital on Dec. 8th, 1905, suffering from erythema nodosum. She had always enjoyed good health and had no family or personal history of rheumatism. On admission the temperature was 101°F ., the pulse was 100, and the respirations were 30. The rash, which had been out for 14 days, was thickest on the extensor surfaces of the limbs in their outer aspect just above the knees; it was also present on the extensor aspect of the legs and the ulnar side of the forearms. There were patches of desquamation on both arms and legs. There were oedema of the legs and pain in the knees and stiffness and pain in the elbows and carpo-metacarpal joints of the hands. There was no sweating. There was a systolic apical bruit over the heart conducted outwards. The pulse tension was high and there was a trace of albumin in the urine. The blood showed: hæmoglobin, 83 per cent.; red cells, 4,200,000; and white cells, 20,000 per cubic millimetre. A differential count showed: finely granular oxyphile leucocytes, 74 per cent.; coarsely granular oxyphile leucocytes, 1 per cent.; large hyaline cells, 7 per cent.; and lymphocytes, 18 per cent. There was slight bronchitis. The teeth were defective and the gums were very foul. The patient was given 20 grains of sodium salicylate every four hours, and the temperature, which had risen on one occasion to 102°F ., was normal on the fourth day. On the night of the fifth day she was noisy and delirious and the salicylate was stopped. The temperature then rose to 100°F ., and remained above normal for eight days, during which time the patient was given 15 grains of aspirin three times a day. The rash disappeared on Dec. 21st (27 days from its first appearance), leaving profuse desquamation, and on the 29th there was still complaint of pain and stiffness in the joints. The apical bruit, which had on occasions quite disappeared, was still faintly audible when the patient left the hospital on Jan. 20th, 1906. The illness had lasted eight weeks.

Such a case as this serves to show the close resemblance there is clinically between erythema nodosum and acute rheumatism, and we may now compare seriatim the predisposing causes of the two diseases.

Age.—Erythema nodosum is essentially a disease of youth and adolescence, the majority of cases occurring during the second and third decades of life. Thus of 125 cases:—

25 cases, or 20.0 per cent. of the total occurred in the 1st decade.	
51 " 40.8 " " "	2nd "
8 " 22.4 " " "	3rd "
13 " 10.4 " " "	4th "
3 " 2.4 " " "	5th "
3 " 2.4 " " "	6th "
2 " 1.6 " " "	7th "
No. 4352	

The age distribution of this disease, therefore, closely approximates to that of acute rheumatism, as may be evidenced from a table which I have published elsewhere¹: First decade, 8.3 per cent.; second decade, 31.6 per cent.; third decade, 24.3 per cent.; fourth decade, 23.3 per cent.; fifth decade, 9.3 per cent.; and sixth decade, 3.1 per cent. It is unusual for erythema nodosum to occur in infancy or old age. The youngest case in my series was three years old and the oldest 63.

Sex.—Whilst acute rheumatism attacks males more than females, erythema nodosum is nearly three times as common amongst women. In the present series of cases 36 were males and 89 were females. As age advances the proportion of women to men attacked becomes higher, the converse to what is seen in acute rheumatism.

Season.—The incidence curve of acute rheumatism presents, it will be remembered, a sharp autumnal rise. It is a curve closely resembling that of scarlet fever and erysipelas. The incidence curve of erythema nodosum shows no such rise. Of 139 cases 32 occurred in the first quarter of the year, 37 in the second, 26 in the third, and 44 in the fourth.

Previous illness.—The prodromal symptoms of erythema nodosum may extend over a period of from one to three or four weeks. They are malaise, fever, headache, pains in the limbs, dyspepsia, and tonsillitis. They are often misinterpreted and a diagnosis of rheumatism, influenza, gastric fever, or broncho-pneumonia is made, and when later the typical rash appears it is regarded as secondary in character. There is, however, but little evidence to prove that erythema nodosum is secondary to any infective process unless it be acute rheumatism. In considering the relationship between erythema nodosum and rheumatism too much importance must not be attached to the existence of febrile arthritis, a symptom which is met with in many diseases other than rheumatism, and it must be remembered that the arthritis of erythema nodosum is in many ways very different in character from that of rheumatic fever. A correct personal and family history would throw much light upon this point, but observers have differed widely in their estimates. Thus Lenden says: "Out of 63 cases distributed amongst 49 families, a family history of rheumatic fever is not recorded once, and in the previous histories of the patients themselves there were only two mentions of rheumatic fever." Goodhart and Still found a rheumatic history in 19 of 29 cases. In a series of 48 cases of erythema nodosum occurring in Bristol three had suffered from rheumatic fever, one from chorea, and one from "growing pains." A mitral regurgitant bruit was present in one who had suffered from rheumatic fever, also in the patient who had suffered from "growing pains," whilst a second who had suffered from rheumatic fever had a presystolic bruit. Six other patients, none of whom gave a previous history of rheumatism, were found to have cardiac bruits (five systolic and one presystolic). Three patients had bruits which were regarded as probably benign in origin. Thus there was the possibility of a rheumatic origin in 11 out of 48 cases (22.9 per cent.). I have no means of judging of the prevalence of rheumatism amongst the class of patients frequenting our hospitals but amongst public school boys rheumatic stigmata are found in just under 3 per cent. It should be mentioned here, however, that erythema nodosum has been observed in gonorrhœal rheumatism. I have seen one such case myself and Hermann records eight undoubted cases.² I have made a bacteriological examination of the blood in a severe case of erythema nodosum but found it sterile, and Fussell, who examined serum from artificial blisters in cases of erythema nodosum, found no specific organism.³ Lenden, too, records a negative result.

From a review of the foregoing facts we find that the evidence of a relationship between erythema nodosum and rheumatism is of a conflicting nature. Whilst the age-incidence of the two diseases coincides there is a marked difference in their prevalence amongst the two sexes, and whilst valvular heart affections appear to be more common amongst sufferers from this disease than amongst the population generally, yet there is not that characteristic seasonal rise of autumnal incidence such as we see in acute rheumatism.

It now remains for us to examine whether the signs and symptoms of the two diseases are in any way similar.

Arthritis.—The arthritis of erythema nodosum may assume

¹ The Rheumatic Diseases (John Lane)
² Münchener Medizinische Wochenschrift, Sept. 5th, 1895.
³ Medical Record, May 12th, 1896.

various forms. The commonest form is pain in the joints without any objective redness or swelling and but slight tenderness on movement. This is strictly comparable to the arthritis of subacute rheumatism. In some cases, however, the joints present rather the appearance of gout. The swelling is hot, red, oedematous, and spreads beyond the immediate neighbourhood of the joint. It is, however, never extremely painful and in spite of the swelling patients can tolerate considerable movement. In yet other cases the joints are enlarged but there is not redness or oedema and the picture is that of gonorrhœal rheumatism or rheumatoid arthritis. The joint pains are not relieved by salicylates.

Temperature.—In the majority of cases of erythema nodosum seen in out-patient hospital practice the temperature is not raised. In acute cases, however, it may rise to 103° or 104°. The peculiar features of the pyrexia are that the rise may take place some days before arthritis or rash appears, and it may persist for three or four weeks in spite of the administration of salicylates. It often takes on an intermittent character.

The rash.—Erythema nodosum is not infrequently associated with other forms of erythema—papular and circinate—such as are observed sometimes in acute rheumatism.

Bronchitis frequently accompanies erythema nodosum. Less frequently it is seen in acute rheumatism.

General.—Lenden found phlyctenulæ in the eyes of 38 per cent. of his cases of erythema nodosum. Personally I have only recently looked for this symptom and up to the present have found it but very rarely. Phlyctenulæ have not been described as associated with any rheumatic conditions. Another point of difference between this disease and rheumatic fever is that whilst in the latter relapses and recurrences are of frequent occurrence, a relapse in erythema nodosum is rare and a second attack quite exceptional. I have recorded one case where a second attack occurred after an interval of more than 50 years.

Erythema nodosum is not characterised generally by any great constitutional disturbance but in severe cases the patient may be delirious, and one young woman sent into the Bristol General Hospital under my care as suffering from enteric fever was comatose for two days. In rheumatic fever it is quite exceptional to find delirium and coma apart from hyperpyrexia. I think that the delirium in erythema nodosum is often the result of the large doses of salicylate which are given, patients suffering from this disease, unlike rheumatic patients, being very intolerant of the drug. The long prodromal period is unlike the onset of rheumatic fever where the disease is seldom presaged by long-continued malaise. I have already referred to the fact that the salicylates do not relieve the joint pains or reduce the pyrexia of erythema nodosum.

Table showing Differences between Acute Rheumatism and Erythema Nodosum.

Rheumatism.	Erythema nodosum.
Age: Youth and adolescence.	Youth and adolescence.
Sex: Males.	Females.
Season: Autumn.	No seasonal variation.
History or signs of past rheumatism: Present.	Present, but less frequent.
Micrococci found.	Not found.
Joints: Tender and of characteristic appearance.	Seldom tender; appearance varied.
Prodromata: Uncommon and of brief duration.	Frequent; long continued.
Erythematous rashes.	Erythematous rashes.
Phlyctenulæ: Not found.	Occur in 38 per cent. of cases (Lenden).
Relapses and recurrences: Frequent.	Rare.
Endocarditis: In about 30 per cent. of cases.	In from 10 to 20 per cent. of cases.
Salicylates relieve.	No effect, but may excite delirium.

Recently a small boy came under my care suffering from erythema nodosum, and on inquiry I found that his sister had a similar attack three weeks previously. Lenden reports several such cases, but they do not point conclusively to the infective nature of the complaint, and indeed may indicate a common rheumatic taint. Cases of erythema

nodosum occur sometimes in groups but no epidemic of the disease has ever been recorded.

The evidence which I have brought forward is, of course too conflicting to enable us to say definitely whether we have in this condition merely a rheumatic symptom or a definite disease, but there is, in my opinion, much to support the view that erythema nodosum is a specific acute febrile disorder; that infection takes place through the tonsils and lungs; that after a prolonged incubation period and period of prodromal symptoms a specific rash appears; and that convalescence is accompanied by profound anæmia and malaise.

SPIRILLUM FEVER IN UGANDA.

By R. U. MOFFAT, O.M.G., M.B., O.M. EDIN.,
LATE PRINCIPAL MEDICAL OFFICER OF UGANDA AND THE EAST AFRICA
PROTECTORATES.

It has long been known that spirillum fever is a febrile disease caused by the presence of a species of spirochaeta in the blood. It was first described under the name of "famine" or "relapsing" fever, but it has no essential connexion with famine and in its clinical course and its tendency to relapse it differs but in a slight degree from some other fevers. In the absence of a microscopic examination of the blood it is at times most difficult to make a diagnosis and reliance has to be placed on clinical symptoms and physical signs rather than on the temperature chart. As showing how an unsuitable name may mislead I might mention that ten years ago, in Uganda, I strongly suspected the presence of so called relapsing fever on clinical grounds, but concluded that I was mistaken—first, because the disease I met with had no relation whatever to famine, and secondly, because in many cases the typical relapses did not take place and my temperature charts showed absolutely no resemblance to those portrayed as characteristic of the disease. The name "tick fever" is also objectionable, for though it has been shown by Dutton, Todd, and Koch that it is transmitted by ticks, it is quite possible that there may be other human diseases which are carried in like manner. To my mind it has been too hastily assumed that spirillum fever is identical with a disease called tick fever, which has long been known in the region of the Zambesi. If the accounts given of the latter are correct its clinical features are quite unlike those of spirillum fever as met with in Uganda, and if it should be proved that they are distinct diseases much confusion will result from this nomenclature. Already the term "tick fever" is often applied to a cattle disease which is transmitted by ticks, and it is not uncommon to hear spirillum fever referred to by the laity and by inexperienced members of the profession as though it were the same disease as that caused in cattle by a totally different organism. It seems preferable, therefore, to name the disease after the organism which causes it rather than after its transmitting agent or some feature which is by no means characteristic.

The disease is certainly not a new one in Uganda, though in times past it was probably often mistaken for malaria. There is no doubt, however, that it is becoming more prevalent and this is in great measure due to the increased traffic on the main roads, for it is in the tick-infected camps along these roads that infection is most commonly contracted. Owing to exigencies of food and water suitable camping-grounds are only to be found at certain places and these caravans in a constant stream make use of these nightly. Once the ticks become infected it is easy to see how the disease is disseminated, and, indeed, the risk of infection is so great that it constitutes one of the most serious dangers and drawbacks to travel in Uganda at the present time.

Incubation period.—In the tick fever of the Zambesi it is stated that acute symptoms follow a few hours after the bite of a tick, but in spirillum fever I have never satisfied myself of a case in which the incubation period was less than seven days and in this particular, therefore, the two diseases differ materially. It would seem that in a susceptible subject the incubation period varies from seven to ten days, but it may be much longer as a result of a partial immunity either natural or acquired. There is no doubt that one attack does confer some measure of immunity and after a second the immunity probably becomes complete, at any rate for a time.

I had a case in a native which must either have been an instance of an unusually late relapse after six months or a

and infection. In another case the patient had a second attack a year after the first and in both these cases only one attack occurred in the second infection. A case in a European is also suggestive. In this instance the patient had spirillum fever with five relapses. After an interval of a month and a half months he was exposed to the risk of fresh infection whilst travelling, but he had no definite remembrance of being bitten by ticks. A month later he had a fresh attack lasting three days; spirilla were found, but scarcely. After an interval of 19 days he had a relapse; this time also the parasites were very few in number. Further relapses took place and this irregular course and long period of incubation were no doubt due to a partial immunity acquired from the first infection. Among natives quite common for one single attack to occur without any relapses and the disease is so prevalent that it is not reasonable to assume that such patients have had it before.

Number of relapses.—Owing to the long-drawn-out course of the disease it is difficult to keep patients, especially natives, under observation throughout the whole time. During the apyretic periods the general health may be such that patients can pursue their ordinary avocations and they usually refuse to stay in hospital. Thus, although about 60 cases came under my observation during the last year I was in Uganda, I only obtained a fairly complete record in 30 of them, as follows: In 21 cases there was one initial attack without any relapse; in two cases there were two attacks (one initial and one relapse); in one case, three attacks (one initial and two relapses); in three cases, four attacks (one initial and three relapses); in two cases, five attacks (one initial and four relapses); and in one case, six attacks (one initial and five relapses). It is worth pointing out that in all the cases in which there were more than three attacks the patients belonged to a part of the country where the disease is much less common and consequently they were more likely to be susceptible. As a rule, in a susceptible subject the initial attack is followed by from three to five relapses. If only two relapses occur I am inclined to suspect a partial degree of immunity.

Period of intermission.—In the 30 cases to which reference has been made this varied as follows: Between the initial attack and the first relapse from five to nine days; between the first relapse and the second relapse, from five to eight days; between the second and third relapse, from five to nine days; between the third and fourth relapse, from eight to 26 days; and between the fourth and fifth relapse it was eight days in the one case.

In some cases, not included among the above, as they were only under observation for a short time, the first relapses occurred after apyretic periods of one, two, and three days. I am inclined to regard these as due to separate infections at different times. When a man is travelling he runs some risk of being bitten every night by infected ticks, and possibly re-infection after a short interval will result in the appearance of two batches of parasites of different ages and origins. This may account for the irregularity with which the earlier attacks sometimes follow one another. I am of opinion that if a period of ten days passes without a relapse none need be anticipated, but when once a single relapse has occurred the subsequent intervals are very irregular and tend to grow longer. The final relapse is usually a slight one, separated from the previous one by an interval of a fortnight or three weeks.

Duration of the attacks.—From three to four days represent the usual length of an attack, but the later ones tend to be shorter. Very often the last is characterised by a single rise of temperature, persisting for a few hours, and followed by a rapid fall to normal.

Presence of parasites.—In the earlier attacks parasites are generally more numerous than in the later ones, in which they may be excessively scarce. This does not always hold good, for at times they are found plentifully even in the later relapses. Towards the end of an attack they begin to disappear even before the temperature has fallen to normal. In one fatal case complicated with tuberculous meningitis spirilla were found even when there was no rise of temperature. In this instance the patient was admitted with a history of several days' acute illness, which from other evidence I judged to have been spirillum fever. His temperature was, however, normal, and the blood examination proved negative. He was kept in hospital for observation,

and though for three days he had no rise of temperature his condition grew steadily worse, serious cerebral symptoms supervening. His blood was examined carefully each day but nothing was found. Finally, being convinced that he had had spirillum fever, I punctured his liver, which was enlarged, and in a smear of blood thus obtained I found spirilla in very large numbers. His finger blood was then again examined and parasites were found, though not so numerous as in the liver-blood. The patient died on the next day and the post mortem examination revealed the fact that he had tuberculous meningitis. On the day that the parasites were found in the liver they had appeared, as was subsequently shown, in the peripheral circulation, but possibly they could have been demonstrated earlier in the liver and in an obscure case where the diagnosis was a matter of urgency, liver-puncture might be justifiable.

Symptoms.—A feeling of malaise, headache, and distaste for food generally precede an attack, coupled with pains in the back and limbs. A slight increase in temperature very soon shows itself and when the acute symptoms develop it rises rapidly. High temperatures are the rule, as will be seen from the following figures: In two of the 30 cases referred to above the maximum temperature was 106° F; in 10 cases it was from 105° to 105·8°; in six it was from 104° to 104·8°; in seven it was from 103° to 103·8°; and in five it was 102° and under. During the course of an attack slight variations of a degree or two occur, not always in relation to the time of day, and, speaking generally, it may be said that the temperature fluctuates but little, and that a decided and sudden fall heralds the approaching termination of an attack. In most cases the temperature then falls quickly to normal, but sometimes a degree or a degree and a half persists for two or three days after the crisis. The skin is hot and dry and the face flushed. In one case in a European a profuse erythematous papular eruption appeared during his first attack and persisted for 48 hours. It covered the face, limbs, and whole body. Whether or not it had any connexion with the disease it is difficult to say, but possibly it occurs frequently, for a rash of this nature might be easily overlooked on a black skin.

Digestive system.—The appearance of the tongue is quite characteristic; it is moist, flabby, and deeply coated all over with white fur. Excessive vomiting is a prominent symptom among European patients, less so among natives. The bowels are, as a rule, constipated, unlike what is said to be the case in Zambesi tick fever, in which purging is spoken of as a marked symptom. In only two cases have I seen purging, and in both of these the patients had ankylostomiasis, which in itself would account for the bloody diarrhoea that was present. Slight jaundice is quite common. The liver and the spleen are generally enlarged and very tender; sometimes only the former is affected.

Respiratory system.—Quick breathing, slight cough, and diffuse pains in the chest are nearly always present, but in a certain proportion of cases these symptoms are intensified and accompanied by all the signs of lobar pneumonia. There are dullness over one or both bases, harsh tubular breathing, great pain, and thick blood-stained sputum. Some years ago I drew attention to the frequency in Uganda of a form of pneumonia which ran a very short course, and judging from my later experience I believe that these were merely examples of the pneumonic form of spirillum fever. The signs and symptoms disappear at once with the termination of the attack, with a rapidity which is most bewildering, if a diagnosis of pneumonia has been made from physical signs without reference to the blood. As a rule, these pneumonic attacks only occur with any intensity in the initial attack of spirillum fever. In the subsequent relapses there may only be the usual quick breathing and slight cough. Spirilla can be found in large numbers in the bloody sputum, and no doubt in these cases the lung vessels are choked with parasites.

Circulatory system.—During the pyrexia the pulse is very rapid; it may be 150 or more. Præcordial pain and oppression are often complained of and the heart muscle appears to suffer, for a tendency to slight attacks of syncope following exertion or excitement is very common. This persists for some days after the febrile period.

Nervous system.—There may be slight incoherence and excitement when the temperature is high, but delirium is not common. Persistent and excruciating headache is a constant feature and in some cases causes acute torture. It is accompanied by actual tenderness of the scalp, which

may be so great that the act of brushing the hair is unbearable. This headache persists sometimes for several days after the temperature has fallen to normal. Unilateral facial paralysis occasionally follows and may last for a few weeks.

Eye symptoms.—A curious condition affecting the eyes frequently occurs. Both eyes may be affected, simultaneously or in succession, but most frequently it is unilateral. It does not come on, as a rule, until after the first relapse and it may be much later. The symptoms consist of an injection of the deeper vessels of the sclera around the cornea, not unlike that seen in an ordinary iritis, but the iris looks quite clear and on cursory examination seems mobile. There are pain, lacrymation, and photophobia. I had long been familiar with this condition, which is very commonly seen, and in default of a better name was in the habit of calling it a scleritis. Eventually I observed that it was associated with spirillum fever and on more careful examination it was apparent that in spite of its deceptive appearance the iris was in reality affected. If atropine be instilled it may be observed that there are some adhesions, but these are rarely tight; in fact, they may be overlooked entirely unless the eye is watched during the time when the atropine is beginning to act. In mild cases the adhesions are so slight that in a very short time the dilatation is complete and uniform. The severer forms of the condition at once suggest iritis, and differ but little from the ordinary inflammatory form of that disease, but the important point to which I want to draw attention is that the mild type associated with a clear and apparently mobile iris is in reality an affection of that organ. On examining with the ophthalmoscope it will be noted that there is on the lens an abundant deposit of pigment, which in my experience occurs far more frequently in this disease than in an ordinary iritis. Often it occurs in the form of a complete ring with a central clear space corresponding to the original pupillary aperture. There is turbidity of the vitreous, so that it may be impossible to obtain a clear view of the fundus. The patient complains of a cloud before his eyes. This symptom persists for some weeks after all injection and other signs have passed off, and may be a source of great anxiety. A reassuring prognosis may, however, be given, for eventually the vision is completely restored by the disappearance of the pigmentary deposit. My own impression with regard to this affection is that it is not primarily a real inflammatory iritis, but that it is a condition resulting from thrombosis in the vessels of the ciliary body and iris, leading possibly to hæmorrhages into the vitreous. At times it does develop into an acute iritis and the adhesions which then form are of the usual kind. I have seen in a neglected case both pupils so firmly bound down that I had eventually to perform an iridectomy. As a rule, however, there seems to be no tendency towards the formation of tight adhesions, even if the condition is untreated, but in cases where no steps have been taken to insure dilatation of the pupil a large amount of pigment deposit may be expected, and to avoid this atropine should be instilled immediately any eye symptoms develop.

Diagnosis.—The spirochætae can easily be found in fresh blood if present in large numbers, but a thin, evenly-spread film is quite unsuitable and in such they may be overlooked even when numerous. A film of moderate thickness is preferable, and in such the agglomerated masses of corpuscles will sometimes be seen vibrating from the movements of the contained parasites if the latter are sufficiently plentiful, and by careful focussing they may be seen semidetached wriggling in the surrounding serum. Being very refractile they are best seen with little light and appear as rapidly moving threads; sometimes they may be made out quite distinctly moving over and against the dark background of a thick layer of corpuscles. There is no doubt, however, that they are much more easily found in stained preparations. I have tried the two methods side by side in the same case and after a vain search through the fresh film I found them at once in the stained one. The quickest way is to take a fresh film and a dry one at the same time. A few minutes are devoted to the former and if the parasites are numerous they will at once be seen and the trouble of staining is avoided. If the search proves negative staining can be proceeded with. I have for the most part used Leishman's stain, which is simple and effective, and the parasites can easily be seen under a sixth. At times they are very sparse, necessitating a prolonged search through several slides. In the absence of means for making a blood

examination it is not possible to make an absolutely definite diagnosis. A history of previous tick bites or of a possible exposure to such will afford strong suspicion as to the nature of the fever but in places where the disease is endemic there are many other biting things and people are so accustomed to their attacks that very often there will be no distinct remembrance of such. The disease with which it is most likely to be confused is malaria. In its onset it differs from it in the absence of any rigor, though it must be remembered that in the malignant tertian the rigor is represented often by a slight and evanescent feeling of chilliness, but otherwise the initial symptoms are very much alike, though, as a rule, they are more aggravated in spirillum fever, especially the headache and vomiting. In the greater number of cases of malaria there is no particular enlargement or tenderness about the liver, whereas in spirillum fever they are almost constant features. The splenic enlargement is common to both. The appearance of the tongue, with its thick, creamy-white deposit of fur, is quite unlike the dirty, dry tongue of malaria. As regards the temperature, there is usually in malaria a distinct tendency to intermission or, at any rate, a marked remission, such being generally preceded by profuse sweating. Spirillum fever attacks are sometimes so short that a sudden termination cannot be attributed to the influence of any remedy administered, and therefore the action of quinine on the temperature cannot be relied upon as a means of diagnosis, except to exclude malaria when the drug fails. The quick breathing and pain in the chest seen in spirillum fever do not occur in malaria. In the pneumonic form a diagnosis can only be made by watching the course of the disease, but it may be noted that the physical signs in the chest not only disappear but develop much more rapidly than they do in an ordinary pneumonia.

The eye symptoms point very strongly towards spirillum fever. I formerly believed that malarial iritis was a common complication of that disease, but since I began to depend for a diagnosis on blood examination I have not seen a case of iritis following malaria. Probably in my earlier cases the antecedent fever was spirillum.

Prognosis.—I have myself only seen one fatal case, already referred to, in which the actual cause of death was tuberculous meningitis. There is this to be said, that most of the cases which came under my notice were amongst able-bodied men and women, and in such the prognosis is good as regards recovery, though the attacks cause much acute suffering. Patients who have a series of relapses become very debilitated but there is no obvious anaemia. Accurate investigations in regard to this point are required. Children take the disease badly and some of the worst cases I have seen were among those under ten years of age. In very young children, old people, and other debilitated subjects the prognosis is probably less hopeful, especially if there is any cardiac weakness present. Pregnant women nearly always abort, and I know of one case in which this complication proved fatal.

Treatment.—So far I cannot speak with confidence in regard to any specific line of treatment. I tried arsenic hypodermically in a large number of my cases, but there is always a fallacy attending experiments in treatment in that the course of the disease may be modified by the presence of a partial immunity. My own impression is, however, that arsenic does tend to decrease the number of relapses. Acting on the assumption that syphilis is caused by the spirochæta pallida, I thought that possibly the antidote for that disease might prove effective in spirillum fever. Not only did it have no effect, but in one case a syphilitic patient who had been under my care for two months, and had taken mercury during the whole time, became infected with and developed spirillum fever which ran its usual course. For the actual attacks symptomatic treatment must be adopted. A smart purge at the outset is beneficial. The headache is sometimes most intractable and may require the hypodermic administration of morphia which tends also to allay the vomiting. Ordinary antipyretics are practically useless; with young children, to whom a high temperature is dangerous, the cold bath or sponging may relieve the urgency of the situation. Great care should be taken to avoid exertion or excitement, not only during the attack but for some days subsequently, as a fatal syncope might result from such. On the first sign of any complaint about the eyes atropine should be instilled and the pupil kept dilated.

Harley-street, W.

X RAYS IN THE TREATMENT OF CARCINOMA AND SARCOMA.¹

By CHISHOLM WILLIAMS, F.R.C.S. EDIN., &c.,
LECTURO-THERAPIST AT THE WEST LONDON HOSPITAL; SURGEON
TO THE CITY ORTHOPÆDIC HOSPITAL, &c.

IN 1905 I published a paper in THE LANCET, entitled "X Rays in the Treatment of Cancer,"² illustrating my remarks with a brief account of ten cases of undoubted carcinoma and sarcoma which had been brought to a successful issue by means of the rays. The earliest case that I have had to treat was sent to me in February, 1900. There was a deep epitheliomatous ulceration of the tongue in a man, aged 61 years. All one can say of that case is that the pain seemed lessened; the treatment, such as it was, was kept up for four months, during the whole of which time the patient steadily lost weight, on the average about a pound a week. From past experience of other early cases and my present knowledge I am led to believe that he did not have one-twentieth of the dose he should have had; one was so fearful at that time of inflammation of the mouth that the slightest reaction was considered the forerunner of that bugbear "dermatitis." The first 16 cases all succumbed within eight months of commencing treatment; this was most discouraging, but still alleviation of pain was produced in some in such a marked degree that it encouraged me to persist. The seventeenth patient, however, gave me much encouragement; he was a man, aged 59 years. In August, 1900, I had what I consider another hopeful case, a person of a man, aged 33 years. In April, 1900, I removed a small tumour from the left parotid region, which had first been noticed in the preceding January. The incision healed by first intention and the Clinical Research Association reported on the growth that it was "a fibro-sarcoma with spindle cells." Four months after, in August, it had recurred in the shape of a lump of the size of a walnut, fairly hard and adherent to the skin and underlying tissues. The patient was treated to 13 applications of about five minutes each with a fairly soft tube and through a lead shield, the shield being of a thickness of one pound to the square foot. During the treatment a slight dermatitis was produced to the degree of dry exfoliation. This was quite unintentional, but the rapidity of the disappearance led me to think a great deal about the subject of the necessity or otherwise of a "reaction." There has been no recurrence during the past five and a half years. The next patient was a single woman, aged 42 years (sent by Dr. H. V. Griffiths). In June, 1899, the late Mr. Christopher Heath removed the left breast and glands in the axilla for scirrhus carcinoma. There was recurrence in the scar and amput about 11 months after. A second operation was performed in March, 1900, and eight months later an ulcerated lump formed in the axilla discharging thin serous fluid tinged with blood. The Clinical Research Association reported on a minute portion "consists of scirrhus carcinoma cells." X ray treatment was commenced in November, 1900, with daily exposures of ten minutes each sitting; a medium hard tube was used at a distance of four inches between glass and skin. After 16 applications a dermatitis was set up; it consisted of a deep erythematous blush over the whole of the left chest and upper arm. Around the scar for a few inches were a multitude of bullæ each of about the size of a millet seed. There was a cessation of treatment for about five weeks. During which time the patient went to the seaside. On her return the greater part of the area was deeply pigmented and about the middle some dry exfoliation was seen. She was treated for a further six weeks by two applications a week with a fairly hard tube at a distance of eight inches about five minutes each sitting. In all, 23 exposures were given. There has been no recurrence during the past four and a half years and the patient is still in excellent health.

Theories.—Several theories have been advanced to account for the action of the x rays on malignant growths. And in my opinion they all seem to point to a leucocytosis being ultimately produced in or around the growths. According to Legros x rays have a special selective action on new

growths—the cell nuclei swell, do not stain well, the outlines of the cells become indistinct and fuse, the protoplasm becomes irregular, is invaded by leucocytes and absorbed, leaving a network of dense connective tissues containing vessels with thickened walls from endo- and peri-arteritis due to the rays. No theory at the present time is entirely satisfactory, but it is encouraging to know that the action of the x rays on the blood is gradually taking shape. Several of our members are obtaining excellent results in leucocythæmia and allied conditions which may solve our difficulties regarding the theory of the action of x rays not only in cancer but in other divers diseases.

Reaction.—Reaction in the part to be treated is a vexed question among some electro-therapists. For my part, I am convinced from practical experience that some sort of reaction is absolutely necessary. It may not always be seen and requires much watchfulness on the part of the operator. My worst failures have been those in which no visible reaction could be seen either of the skin or, more important, of the lump itself. The reaction may take a visible form of redness in the mass if protruding through the skin or round the edges if an ulcer, swelling or hardness of the tumour, increased heat, perhaps in some cases increased pain or other vague undefined feelings to the patients. If a discharge be present it soon takes on a more healthy action both as regards appearance and odour. Frequently I have seen masses break down and slough away. Sometimes there is pent-up pus, with elevation of temperature and night sweats. In one case of sarcoma of the side of the neck the growth became after one application of new soft tube, 20 minutes at three inches, almost black, and the turgescence of the overlying blood-vessels was very great. After the sixth dose the mass was fluctuating; it burst and discharged pus with large pieces of greenish fætid slough which microscopically showed intense degeneration (wash-leather slough). In some growths the reaction may affect the patient in a general way. Symptoms such as slight increase of bodily heat at night, sweatings, headache, malaise, thirst, and loss of appetite may be observed. This generally yields to a cessation of treatment for some time. This is most seen in large growths which are not ulcerated and have no exits for the products of disintegration, the patient having to absorb them and get rid of them by the usual channels.

Pre-operative and post-operative treatment.—If the theories mentioned are proved to be correct then it would seem to point to the advisability of using the x rays in all cases prior to operation, more especially to the hard and usually slower growing varieties. The rays might be used with advantage during that period, sometimes weeks, during which the patient is being prepared for operation. The mildest dosage should be used and the effects on the growth or glands carefully noted. It has been objected to by some that x rays should not be used as a pre-operative measure on the following grounds: that (1) the agent has not yet been proved curative, and (2) the serious risk of extension of the disease to inaccessible glands or other regions by metastasis during the period of trial. In answer to the first objection I am of opinion that the rays have been proved curative to a certain degree, not as yet absolute it is true. To the second objection I would only advise their employment at present to a few weeks at the most prior to the operation. In inoperable and recurrent cases the rays should always be used. Post-operative treatment may be used directly the scar is healed or even before that time if it shows the slightest appearance of being sluggish in the healing. A nodule of the size of a pea should have immediate treatment whether in the scar or not; this requires for its proper fulfilment constant observation by the medical attendant. In recurrent cases after operation the less "recurrence" there is to treat the easier it will be for the application of the rays to effect a favourable result. The best cases are those where the disease is strictly local. Nevertheless, the rays have given much promise of well-doing that in the present state of our knowledge it would be unwise to refuse treatment to any case on the score of extensiveness of growth. Again, we must always remember that pain in any case may be relieved in a remarkable manner. Also, the mere fact that something is being attempted for the patients has often proved to have extraordinary effect on the minds and very materially assists them to bear their heavy burden.

Causes of failure to arrest the progress of the growth.—Failure may be attributed to several things. Amongst the most important will probably be inexperience on the part of the medical man; the vagaries of the apparatus; too mild or

¹ Abstract of a paper read before the British Electro-Therapeutic Society, March 23rd, 1905.

³ THE LANCET, Nov. 4th, 1905, p. 1320.

too energetic treatment; the case being hopeless on account of either the growth being too diffuse, or having become disseminated throughout the internal organs of the body; or the patient's general vitality having been lowered by previous suffering. Pain from the treatment is never severe but when added to the pain of the growth the total may be considerable; as a rule after a few applications the pain is very materially relieved; I have had many cases where opiates have been entirely dispensed with shortly after commencing treatment. In a large mass if the central parts show a tendency to break down into pus without an efficient exit the pain may be considerable. Hot fomentations in suitable cases seem to effect much good. Violet leaves being still the fashion they may be made into poultices or the infusion used as fomentations. Non-perseverance on the part of the patient may arise either from getting a measure of relief which frequently passes our most sanguine expectations and which the patient believes to be permanent, or from the patient giving up all hope of a cure owing to the somewhat tedious course of the treatment. Care must be taken that the part be transparent to the x rays. I was once consulted as to the failure of x rays in a case of fungating sarcoma. It had had two applications a week of x rays for over nine months, and although the tumour had diminished slightly the first two months, it had then rapidly renewed its growth. I found the lump of about the size and shape of a coconut, of ivory whiteness, consisting of over half an inch of hard white china-like material which was found to be due to the large amount of dusting powder used; this had caked and was quite opaque to x rays. The powder contained a very large percentage of zinc oxide. The tube was the original one and gave off a veritable shower of sparks; the spark gap was 12 inches and the current sparked during the whole application. A lay relative had applied the rays and did not consider all was right unless this phenomenon was observed. That was an example of too mild treatment. As an instance of too energetic treatment, in one patient of a very low vitality who suffered from a large inoperable sarcoma involving the whole of the contents and walls of one orbital cavity the treatment which it received for the first six weeks quickly began to shrink it up, then, in spite of my efforts, commenced to enlarge; a new tube was used, and the dose doubled, but unfortunately the whole part sloughed out. Uncontrollable hæmorrhage ensued, which in a few days proved fatal.

Dermatitis; preventive measures.—Considering the prolonged treatment necessary in this class of conditions it is not surprising if we sometimes meet with a dermatitis. In my earlier cases I frequently unwittingly produced a mild dermatitis; we knew less about preventive measures in those days but I am bound to say that some of my best results have had a dermatitis to the extent of dry exfoliation or even slight bullæ. Except in cases where the growth is strictly local, such as epithelioma of the lip, I think it is best not to screen the surrounding parts, so that the rays may reach scattered deposits in the remote tissues. From the knowledge recently gained in the treatment of ringworm by Sabraud's method it is easy so to keep the tubes in a condition that few irritative rays are given off, and although this may unduly prolong the treatment it seems at the present moment to be the best course to pursue. At first I tried a number of substances—aluminium foil earthed, various thicknesses of soft stuffs, clothing, vaseline, and other substances too numerous to mention. My almost immunity from burns to the patient I put down chiefly to the use of medium to hard tubes. Nowadays with the apparatus employed a dermatitis to any extent should be extremely rare and the treatment thereby much curtailed.

Standard dosage.—Would that we could formulate a standard dose as we can in the case of some drugs. At present this appears impossible, but we can only hope that in the near future it will become possible to give an exposure that will produce a definite visible effect. At present we can only compare our work in a very general way, owing chiefly to the divers kind of apparatus in use. The idiosyncrasy of the patient is a factor that cannot be neglected when considering the dosage. My observations lead me to think that fair people burn more quickly than dark and that dark people pigment the more easily. Still it may prove that with increased experience and knowledge of the behaviour of the growth to the x rays and with more regulatable apparatus the idiosyncrasy of the patient will in proportion diminish. With my apparatus as at present arranged one usually finds that a dose of from 3000 to 5000 Röntgen units is

given at each sitting and renewed or increased according to the effect produced. When all is said on behalf of dosage and its measurement, actual experience of the operator is of the first and final importance.

That the pain of malignancy can be much alleviated by x ray treatment is common knowledge among those who have had much experience in this form of treatment. The pain that one sometimes notices in cases where it is obviously due to the dragging or contraction of the scar does not seem to yield so readily as "growth" pain. Pain produced by post-up discharge or the disintegration and liquefaction of the malignant cells can only be relieved by the patient's absorbing powers or by an exit naturally or artificially produced. In uterine cases it is important carefully to distinguish between the period pain and the pain of the growth whilst under treatment. One woman with a cauliflower excrescence of the cervix had had no period for over 14 months prior to the commencement of treatment. In seven weeks with daily applications the growth had disappeared but the whole of the contents of the pelvis were lumpy and matted together. To my great surprise the pain, which had decreased to almost nil, came back with renewed vigour, although the cervix looked perfectly healthy and the excretion was perfectly normal. After eight days I suspended treatment as I thought that the x rays were possibly the cause. The patient returned in a few days with the cheerful intelligence that she was suffering from a copious period, on the cessation of which all pain vanished. Her periods have been most regular since and the parts are gradually assuming their normal condition. There has been no return during the past two years.

Glands.—In the majority of cases that I have had to treat where there was much glandular enlargement it is a curious fact to note that the glands actually infected became of a hardness before they disappeared. One has so often seen the glands depart in such cases that I am led to the conclusion that frequently they are only affected with a simple inflammation from irritation of the secretions of the original growth and not from actual infection. In one patient who had the glands enlarged many months after the breast had been removed and the resulting scar was white and perfect, there were undoubtedly infected, but readily disappeared with a few months' treatment, though this patient succumbed to a recurrence 11 months after, during which time no x rays were applied. In another case, that of a woman, aged 48 years, who had a primary carcinoma of the left mamma, quite two-thirds of the gland was involved and there were many lumps in the axilla which practically filled that space. She had refused any operative measure. Under x rays, administered three times a week for over four months, the lumps cleared up and the breast contained a hard tumour much less than half the whole gland; this was then removed and was proved to be an ordinary cirrhus carcinoma of a very fibroid character. This patient has been since October, 1903, and is at the present time, in excellent health.

I well remember the day on which the evening paper announced Röntgen's brilliant discovery. How at first with a conservatism natural to our profession, we treated it as an exceptionally smart piece of yellow journalism, but within a week we, imperfectly it is true, observed the shadow of the bones in the fingers of our own hand, and our scepticism was turned to astonishment. Proceeding forward we thought it astonishing that some little superficial cancers disappeared, and had not our scepticism received so great a shock about the diagnostic power of the rays we should have been even more sceptical. But the fact remains that most of the little growths can be alleviated by x ray treatment. Who can say how soon in the future with increased knowledge of cancer and of the rays the alleviation of the larger growths may not be attained.

Bedford-square, W.O.

MEDICAL MAGISTRATE.—Mr. Charles Cecil Ballmore, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been added to the commission of the peace for the county of Cornwall.

DEATH OF A CENTENARIAN.—Mrs. Elizabeth Cattle, who celebrated the 103rd anniversary of her birthday on Nov. 24th, 1906, died on Dec. 29th in York, of which city she was a native. About three years ago, on reaching the age of 100 years, she received a sympathetic communication from Queen Alexandra.

TWO CASES OF TRAUMATIC RUPTURE OF THE KIDNEY, IN ONE OF WHICH A SINGLE KIDNEY EXISTED.

BY JAMES GRANT ANDREW, M.O., M.B. GLASG.,
F.F.P.S. GLASG.,

SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

CASE 1.—The patient, a boy, aged 14 years, was admitted to the Victoria Infirmary, Glasgow, on June 5th, 1906, as an urgent case, on the recommendation of Dr. Andrew Buchanan. The following history is obtained from Dr. Graham's report. 11 days previously the patient fell from a cellar. No very distinct account of how he fell could be obtained, as the boy himself did not remember the accident at all clearly. His father was of opinion that he somehow came against the edge of a stair, his abdomen and its lumbar region apparently receiving the brunt of the impact. Two of the boy's companions assisted him home on his arrival there he looked white and felt faint and complained very much of severe abdominal pain. Shortly after getting home he vomited freely and this continued for several days. The vomit, according to his father, contained food quite distinctly up to two days previously, when retching and vomiting ceased and he seemed to be decidedly better. On the day before admission, however, vomiting recurred and generally the boy looked very ill. All along he had complained of pain in his abdomen and in the right loin more particularly. From the day of the accident there had been a considerable quantity of blood present in the urine, and on the previous day there were several large clots present in it. For the first two days after the accident the quantity of urine passed was very small but he was not catheterised. Since then the daily amount passed had been fairly normal. He had no frequency but the pain during micturition, especially on the day when the clots were passed, had been very severe. The micturitions had been quite normal in colour and there had not been at any time bright red blood present or any melæna.

On admission the patient was very blanched. His pulse was 82, soft and dicrotic, but regular. He complained much of pain on the right side but was not restless or sick, and there was nothing to indicate any active hæmorrhage. Examination of the abdomen showed a very distinct bulging in the right lumbar region, a bluish discolouration appearing through the skin. The swelling extended right forward to the middle line and backwards a short distance from the spine and filled up the whole interval between the lower true ribs and the crest of the ilium. It extended also down into the right iliac region, but did not completely fill up this region, a small interval above Poupart's ligament being clear to percussion; the swelling was extremely tender to touch and fluctuant. The left side of the abdomen was soft to palpation and not tender and there was no evidence of free fluid in the abdominal cavity. There was about one and a half inches of liver dulness in the nipple line and the tumour dulness was not continuous with it. The urine contained a considerable quantity of blood diffused through it and albumen but no pus. He was fairly quiet in the early part of the evening and drank freely on account of his thirst. About 9 P.M. he began to complain more of the pain in his side and his temperature dropped two degrees. He did not complain of faintness or dimness of vision, nor did his pulse rise beyond 97, but he looked as if there had been some fresh hæmorrhage. During the first four hours after admission no vomiting occurred, but between 10 and 11 P.M. he had vomited very freely. There was no blood in the vomit. His bowels moved without any aperient. The motion was hard and of natural colour, but there was a distinct amount of blood clotted round the fecal masses. Within the last hour he had developed a slight cough evidently due to upward pressure on the lung. On June 6th his condition was slightly better, the pulse having dropped slightly. There was, however, a distinct increase in the size of the swelling in the loin and as he was suffering very severe pain he was operated on at once.

Operation.—I made an incision in the lumbar region and divided the muscles down to the perirenal fat; this was separated off with the finger, some blood clot was removed, and a large dark encapsuled swelling presented itself. On separating this all round it was seen that the swelling was

within the kidney, the capsule being enormously distended owing to the effused blood in the kidney substance. A small rent in the capsule was enlarged and the contents of the swelling, blood clot and a slight amount of urine, were evacuated. Iodoform gauze was then packed down into the cavity alongside a thick tube. There was a great deal of bleeding, and stuffing was packed tightly into the wound down to the kidney. The tube was led into a bottle and the kidney was drained. The cavity was very large and it was feared that there was a great deal of disorganisation of kidney substance.

In the evening the patient's pulse remained quick and he complained greatly of thirst but during the night was less restless. The wound was redressed at 11 P.M. He had four saline injections per rectum during the night. On June 7th there was slight improvement in the pulse and temperature. Urine was passed both by the tube and in the natural way and it contained a large amount of blood. On the 14th urine was draining freely into the bottle from the lumbar wound. For the last day and a half he had not passed any urine in the ordinary way; a catheter was passed on the previous day but only a few drachms were drawn off and the bladder was not distended. The urine drawn off was quite clear and did not contain any blood. The temperature had been elevated for several nights but the wound looked fairly well and he was altogether much better. On the 22nd the tube was left out of the lumbar wound. There was considerable drainage on to the dressing. The amount of urine passed naturally was now quite normal. On the 30th the lateral wound was healing up.

On July 9th the urine looked clearer; it contained pus, however, in small quantity, but no blood. On the 30th only a slight discharge of urine could be expressed from the wound. The patient was now passing naturally a fair quantity of urine; pus was still present in small amount.

On August 9th the urine was still improving; there was a slight haze of albumen. The temperature showed a tendency to rise if the sinus was not opened up daily. On the 16th the temperature was slightly raised at night again; no pus was present in the discharge and very little in the urine. On the 30th, for the past few days the temperature had been raised and it was feared that there might be some collection or that some ulceration was in progress in the disorganised organ for some blood reappeared in the urine, but the boy did not otherwise complain. On the 31st he had complained very much all night of pain in the old site. It was evident from his appearance that a fresh hæmorrhage was taking place from the kidney. Examination of the right side showed that there was a swelling present passing forwards towards the middle line very much as on admission. The swelling was very tender and the abdominal wall was rigid on the right side. The rest of the abdomen was clear and there was no fluid within the peritoneum.

On Sept. 1st I performed another operation. Laparotomy by a median incision was done and the kidney region was examined. No kidney on the left side could be discovered; it was therefore out of the question to remove the supposed single kidney on the right side. The abdominal wound was then closed and the original incision on the right side opened afresh. There was a great deal of disorganisation, blood clot and blood removed and it was found that a part of the kidney was much injured. The cavity cleared out, flushed, and a large drainage-tube inserted, packing alongside. Later the patient was transfused, 11 P.M. there was no further evidence of hæmorrhage effects. The urine had been passed in fair quantity both naturally and by the tube. On the 2nd he was very restless and this infection, repeatedly. On redressing the wound no changes of condition in the abdominal condition. On the 3rd the anæsthesia do not passed had greatly diminished and vomiting ceased in their light degrees. The boy died on this day.

Permission was granted only to remove the kidneys suffice to John Anderson, pathologist to the infirmary, by appreciable organ thus: "The specimen is an example of a systemic disease of the kidneys on the right side. There was an anæmia; but at the kidney on the left side, and the solitary kidney having been situated in the right lumbar and right iliac region, conferred on the a trilobed appearance externally, with light degrees of infection middle parts and a smaller lobe at the lower pole. The organ weighed fully eight ounces and is not the case with its measurements are 12 cr. disease does not exist transversely at its mesial parts. Thus it follows that at the poles. There were two degrees of the disease depends on

the extent of immunity obtained prior to infection and upon the degree of infection when it occurs. I might point out incidentally that the definite characteristics of both the degree of resistance and that of the opsonic defect would be transmitted to succeeding generations according to the Mendelian law of transmission.

In the light of present clinical knowledge I shall now briefly sketch the more important defensive mechanisms which are brought into play on the occurrence of an unmixt tuberculous infection of moderate severity in the case of an otherwise healthy (?) adult European. The preliminary defensive mechanisms having been overcome, we have to consider, then, the extent and virulence of the infection on the one hand, and the vital resistance of the individual on the other, whether this be acquired or inherited. The site of infection may be on the mucous membrane of the floor of the buccal cavity or in the region of the tonsils, where the accidental presence of other bacilli among the normal flora of the buccal cavity influences the tubercle bacilli favourably or unfavourably, according as the accidental bacilli are certain pneumococci or streptococci which are congenial to the tubercle bacillus, or others which are not. It is well known in regard to this point that the tetanus bacillus, which is normally anaerobic, will nevertheless proliferate easily under aerobic conditions on a culture medium in company with several common saprophytic organisms, such as the ordinary bacteria of decomposition found in a foul lacerated wound. After adapting themselves to their altered environments in such localities and surviving a definite period of incubation the tubercle bacilli tend to undermine the adjacent structures and to move from their extra-corporeal position to other positions which are intra-corporeal. On the one hand, the opsonins present begin to be expended and a further response is evoked; on the other hand, the mechanisms of phagocytosis and segregation are now simultaneously brought into play by virtue of a leucocytosis in which the lymphatic system is mainly concerned. There are evidences of a hyperemia at the site of infection, elevation of the normal bodily temperature, and a fall and rise of the opsonic index, according to the fundamental laws laid down by Sir A. E. Wright. A migration of at least two types of leucocytes takes place in the vicinity of the infection—one of these being concerned with the formation of neoplastic encapsulating tissue for the purpose of segregation and the other type with the carrying on of phagocytosis. With reference to this action it is conceivable that the phagocytes deal with the more advanced and scattered bacilli, especially those that are opsonised, while the other type surround those that are massed together so as to form the tubercles or localised foci and keep them inclosed pending the development of further opsonins and incitor elements.

The expenditure and generation of opsonins depends (1) upon the regulation and degree of mobility of the invading forces; (2) upon the rate and efficiency of the segregations; and (3) upon their location, whether they are in or near to highly vascular tissues (where they are more accessible to the leucocytes) or in remote, less vascularised tissues. The tissues of the adult, being more organised and dense, offer a greater obstacle to the migration of leucocytes in unwonted directions, but the less organised tender tissues of the infant are more permeable. Phagocytosis having been completely effected after opsonisation, and encapsulation established, the acute stage of the malady is tided over and the more subtle, chronic stage of convalescence sets in. Where the encapsulating tissues contain opsonised bacilli only these bacilli probably undergo degeneration and die and if the encapsulating tissues be not too dense to permit of the slow liberation and diffusion of their toxins a stimulus to incitor elements is produced and the phagocytes are incited to penetrate those foci from which they do not emerge again, but the contents of which they neutralise, so forming pus. But there may also be some active foci, the bacilli in which have escaped opsonisation previously to encapsulation; these in due course proliferate and subsequently emerge on moderate bodily exertion, causing auto-inoculations, probably before the system has had time to recuperate from its losses and an exacerbation of the malady occurs. To meet this contingency, however (if the suggestions implied by Dr Paterson be sound), *pari passu* with the phenomena described above, an elaboration of a tuberculo-tropic and antimicrobial vaccine has taken place in the lymphatic glands corresponding to the sites of the original infection. At this stage of the malady these glands are densely, and

therefore more or less imperviously, encapsulated in the neoplastic tissues. These glands having performed this important function now cease to act and become degenerated and cased. The afferent and efferent vessels are blocked within and constricted without. The egress of this substance into the circulation is thus barred when it is most needed and recovery depends on its regulated or accidental admission into the circulation. After the surgical removal of certain tuberculous glands we may find in the unintentional vaccination thus effected an explanation for the occasional disappearance of tuberculous symptoms. This action is similar to the case of certain intra abdominal suspiciously cancerous tumours with glandular involvement, where, after opening the peritoneal cavity, the tumour mass for certain reasons has been left without further operative procedure and in a remarkable manner has been known to disappear subsequently. I merely offer these suggestions on the grounds of the high potency of an almost infinitesimal quantity of such vaccine, where present in the lymphatic system, and the possibility of its accidental admission into the circulation.

It is the purpose of this paper to attempt to demonstrate the theory that the mechanism of the therapeutics of x rays rests upon the induction of an auto-vaccination, subsequent to the resolvent action of the x rays on the rudimentary neoplastic encapsulating tissues about the tuberculous glands, thus rendering the vaccine accessible to the bloodstream. It will also be shown how its effects may be observed by minute temperature reactions, accompanied by similar advances in the opsonic index without negative phases, tested by the periodic estimation of the opsonic index to tubercle bacillus. As a preliminary it will be advisable to give some general account of the effects of x rays upon normal and abnormal tissues.

The x rays are known to have a special selective affinity for morbid tissues, independently of their position or of any inflammatory reaction. This selective action on morbid tissue may proceed without any signs of irritation or any apparent modification of the skin. The dose necessary for the production of an alopecia will naturally be less than that required for the destruction of the granulation tissue of an epithelioma. In the use of other therapeutic agents we are often obliged to vary the dose. A given drug may have a tonic action in a small dose, an emetic action in a moderate dose, and a poisonous action in a large dose. The same may be said of the x rays. Take, for example, their action on the scalp. In small fractional doses they have a stimulating effect on the hair, producing an action similar to that of a rubefacient lotion; whereas in large doses they cause epilation, and in still larger doses vesiculation, ulceration, and sloughing. Again, it is well known that certain drugs have a tendency to accumulate in the system and that in this way minute doses frequently repeated may produce serious results. To some extent this also is true of the x rays when frequently repeated doses are applied over the same spot, but not when these doses are distributed over the body, seeing that the locally absorbed ions are not influenced by the general circulation.¹

Many authorities both in this country and abroad have studied, post mortem, the microscopic appearances of morbid tissues that have during life been subjected therapeutically to the action of x rays, and they have sought to establish the mechanism of its curative effects.

In regard to the therapeutics of x rays Dr. H. Lewis Jones² says, "The gradual onset (of radio-dermatitis) after a latent period, suggests that the lesion (x-ray dermatitis) is a tropho-neurotic one due to the damage sustained by the superficial nerves of the part;" and again later he says, "It will be noticed that nothing is here given on the appearances presented by cutaneous nerves, and this is probably an omission of importance."

Schwartz, working in Holzknecht's laboratory, has further pointed out that the x rays decompose the lecithin in the neurolemma of the nerve filaments, producing meth-lamin. The inference would therefore be that primarily the nerve filaments are acted upon, producing a paresis of the capillaries, followed by a passive hyperemia, and that secondarily an analgesia, and finally a necrosis, follow, with the usual line of demarcation, according to the quantity and the quality of the x rays applied. The subsequent processes of repair, depending on the rate of regeneration of the trophic nerve filaments, are naturally very slow and tedious.

¹ Delor's Radiotherapy.

² Medical Electricity, fourth edition, p. 476.

Dr. J. Belot³ states in regard to lupus after irradiation: "The following is apparently the mechanism of cure by radiotherapy: the hyperemia set up by the x rays provokes an abundant migration of leucocytes from the vessels. As may be seen after a tuberculin (sic) injection, the leucocytic infiltration commences at the periphery of the tubercular focus and penetrates by narrow tracks into the substance of the lupus nodules, these leucocytes being ultimately transformed into fusiform cells and fibrous connective tissues. The presence of these fusiform cells bears witness to the active proliferation of connective tissue. The lupus cells degenerate by vacuolization; the nuclei lose their affinity for stains, necrose, and become absorbed, the diseased tissue being replaced by cicatricial growth. As Schwartz has shown, *all idea of bactericidal action falls to the ground*. The most important point in the case of lupus is the localization of the inflammatory reaction and its concentration exactly at the diseased point, in consequence of the degeneration of the lupus nodules themselves. Both Schwartz and Neisser pointed out that there is in this respect a resemblance between the action of x rays and that of tuberculin, which also sets up inflammatory phenomena that are concentrated on the tuberculous nodules."

It is well known that all neoplastic tissue is a rudimentary replica, almost in every detail, of the tissue affected, and that such tissues are highly susceptible to the influence of x rays and of the less penetrating cathode rays. These stop short of damage to the normal and more organized tissues,

It was at this time that my attention was drawn to Dr. Paterson's article. Shortly afterwards another of the cases of enlarged tuberculous glands came up for treatment and I was enabled by the kindness of Dr. W. E. Facey and Mr. A. B. Bailey of Christchurch to have the patient's opsonic index estimated previously to, and during, a series of irradiations by the x rays.

The patient was a single woman, aged 27 years, an only daughter, both of whose parents were living and well. Her childhood had been spent in London where she had acquired continuous throat trouble and inflammation of both tonsils, which had been partially removed at the age of 11 years. She had suffered much from anæmia as a girl and also from bronchitis and loss of appetite. The patient first came under my medical observation in April, 1906, suffering from moderate constipation. In the month of August following she drew my attention to certain glandular swellings in the neck, more noticeable on the right than on the left side. She had been steadily losing weight during the previous six months. Her record weight had been 9 stones 8 pounds, and she was now 8 stones 2 pounds; her height was 5 feet 4 inches. The body, not so well nourished, but not emaciated, gave the appearance of one in ordinary good health. The temperature had remained subnormal for some months, ranging from 96° to 98° F. The patient's habits were inactive and she was easily fatigued but there were no further symptoms of constitutional disease traceable. The opsonic index to tubercle

Chart showing the variations in the opsonic index.

when they are judiciously applied, and they restore metabolism where it has more or less come to a standstill.

So much, then, for the therapeutic action of the x rays on the normal and abnormal tissues. I now proceed to give cases occurring lately in my own practice upon which the theory of this paper is based. I wish to remark that during the past two years I have utilised these effects of the x rays solely with a view to restoring the natural contour and to removing the disfigurement in females and males in such situations as the cervical, peribronchial and mediastinal regions. In the last case a mass of glands to the left of the sternum had produced an "aneurysmal" bulging of the third, fourth, and fifth sterno costal cartilages and marked cardiac displacement, &c. The invariable results, I need hardly add, were a disappearance of the swellings after alternate soft swellings and shrinkings. Mild toxæmias in the intervals, as one would anticipate, without appreciable rises of temperature, more marked, however, in the mediastinal case, did occur. No symptoms of re-infection were encountered, and, from what has been above stated, this bogey need not be apprehended, except in early acute cases. On the other hand, these cases almost always without exception gained very appreciably in weight and improved in their general health in a remarkable manner. I became curious to explain this fact and as none of their opsonic indices had been estimated it occurred to me that Dr. Paterson's suggestion might account for it.

bacilli on Sept. 1st was 0.5, with brief irradiations on the 2nd, 4th, and 6th; on the 6th it was 0.95, with brief irradiations on the 12th, 13th, and 14th; on the 16th, 0.82, with slight skin reaction and with brief irradiations on the 18th, 19th, and 20th; on the 22nd, 0.90 (the patient had returned after a visit to London); on Oct. 26th, 1.11; on Nov. 1st, 1.09 (the patient throughout the previous day had taken an active part in a bazaar); on the 7th, 0.72, with irradiations on the 10th, 11th, 12th, and 13th; on the 14th, 0.82; and on the 22nd, 1.2. During this period a gain in weight of 9½ pounds took place and a general improvement in health with the disappearance to external observation of the glands in the neck. The temperature had ranged between 97° and 99°, each irradiation being followed by a rise of from 0.5° to 1° in temperature. In the intervals of the irradiations the glands softened, swelled, and shrank, with tenderness on pressure, until they disappeared.

This case is not considered cured nor as yet completed, but the technique necessary for continuing to obtain the opsonic index in this, or in a number of cases, necessarily has its limitations, owing to the expense incurred in obtaining the opsonic index, a matter of about £20 in each case. This method can therefore only be employed in occasional cases where further proof of this important effect of treatment by the x rays may be desired.

The limitation of the phases of the opsonic curve within narrow and normal limits—the entire absence of negative phases, and finally, the minute range of the temperature

³ Radiotherapy, p. 307.

reactions go far, in the opinion of the writer of this paper, to render his theory worthy of consideration.

The radio-therapeutic technique, with radiosometric chart, I propose submitting in due course to *Medical Electricity and Radiology*, in the October number of which journal a significant article from the pen of Dr. H. B. Wilkinson, physician in charge of the San Lazaro Hospital, Manila, appears in an abstract, under the title "The Treatment of Leprosy with the X Rays," to which I would direct the attention of those interested in advanced therapeutics. Of this I will quote one sentence: "Another case was well after 14 treatments. The writer is inclined to believe that when a local lesion of leprosy is treated with the x rays the organisms there localised are killed, and their bodies are absorbed into the system, thereby producing an immunity of the system against the living organisms."

Holzkecht says: "The cure of an infective process is not due to any bactericidal action of the x rays, since the bactericidal dose is many times as great as the curative dose." This theory in regard to the mechanism of x rays is quite compatible with the theory of the parasitic origin of cancer. "Skinner has given a detailed résumé of the hypotheses put forward to explain the cure of malignant tumours by the x rays. According to the third hypothesis cancer is a parasitic disease, and the x rays destroy or hinder the development of the parasites. It may be, however, that the x rays are not destructive to the parasite itself, but in some way modify the tissues so as to prevent its development."

In this reference, Dr. G. H. A. Clowes of the New York State Cancer Laboratory, in his article entitled "A Study of the Influence exerted by a Variety of Physical and Chemical Forces on the Virulence of Carcinoma in Mice" states: "That immune forces are produced in the serum in gradually increasing quantities as the tumour progresses is indicated by the tendency frequently exhibited by tumours to remain stationary, after fairly rapid development, and then subsequently either to grow rapidly or retrogress. In this connexion it must be noted that x rays produce a much more marked effect at this stage, at which apparently the tumour (?) has quite overcome the natural immunity of the mouse, and is developing rapidly."

Dr. Belot thus sums up: "In conclusion, we may say that the x rays exercise a special action on certain cancerous cells, causing their degeneration and absorption, but that the mechanism of the action is still unknown."

I am tempted by the obvious therapeutic parallelism in the recently reputed medicinal agents in cancer to enter into their probable therapeutic values as recorded in the experience of others. I refer to papain, trypsin, and amylopsin, but I will only add that these enzymes, when injected in emulsion into the encapsulating tissues where metabolism has come to a standstill, bring about active resolution (if veins are avoided) by virtue of their proteolytic and diastatic properties on those tissues, when the lesions are accessible and not too deeply situated. They may thus liberate the vaccine when present in the lymphatic glands with the desired result if they do not influence it unfavourably by admixture before neutralisation.

Clinical experience is greatly in advance of the theories hitherto put forward, and I am not in a position at present to make manifest the above theory "by columns of figures and percentages of calculations of cures." I merely venture to submit these observations in the hope that if confirmed by those who have the necessary facilities for working in this department of therapeutics they will afford a solid basis for the scientific employment of radiotherapy, as well as for the proper classification of those conditions in which its use is indicated, and a most important field of medication will thus be opened up among those chronic ailments which occur after middle life and in which ordinary therapeutic measures have so far failed.

TRACHEOTOMY IN SLIGHT RESPIRATORY OBSTRUCTION ASSOCIATED WITH FEBRILE TOXÆMIA.

By A. O. BISSON, M.R.C.S. ENG., L.R.C.P. LOND.,
 JUNIOR ASSISTANT MEDICAL OFFICER, PLAISTOW FEVER HOSPITAL.

In fever practice there is a type of case occasionally encountered in which toxæmia is accompanied by very slight—apparently inconsiderable—obstruction of respiration. Cases of this kind are perhaps commonest in septic scarlet fever with swelling in the faucial region and the naso-pharynx, possibly with some degree of septic laryngitis. A somewhat similar condition, however, is now and then seen in small-pox; one case of this type occurred at Dagenham Hospital during the last epidemic in London. The laryngitis caused a slight degree of obstruction which, owing to the enfeebled state of the patient, soon began to tell on his cardiac condition. Tracheotomy was performed; it was followed by a remarkable improvement and the patient recovered. There is also a septic type of diphtheria defined by Monti in which the larynx is but little affected; there is slight obstruction but it is not progressive and the patient apparently goes downhill as a result of the toxæmia alone. Some years ago, in a case at Plaistow Hospital, the question arose whether the patient's steady loss of ground might not be in part the result of very slight respiratory obstruction—strain on the respiratory muscles and deficiency of oxygen. The result of tracheotomy was a striking improvement in the condition of the patient with ultimate recovery where it seemed hardly possible. In consequence of this result it was laid down as a principle that no patient with slight respiratory obstruction should be allowed to die without tracheotomy having been resorted to. From time to time such cases have occurred at Plaistow Hospital; some of them have been under my care, and it may be of service in calling attention to a procedure so far not emphasised in medical literature. Its importance cannot be measured by the frequency of the cases in which it applies, because when such cases do occur they are of a grave nature, and the operation, as I hope to show, is sometimes life-saving.

INDICATIONS FOR OPERATION.

The indications for tracheotomy in the type of case under consideration are:—

1. *Difficult breathing.*—Owing to the intense congestion of the fauces and the profuse muco-purulent discharge from the naso-pharynx insufficient air reaches the lungs. The patient may breathe with the mouth open and the lower jaw often drops during each inspiration. The breathing is noisy owing to gurgling of the accumulated discharge in the pharynx, stridor being seldom present. The respirations are usually increased in frequency and the *alve nasi* are brought into action; this increase in frequency is not marked and as in definite laryngeal obstruction the respirations may be slower than one might expect from the height of the temperature and the rapidity of the pulse. Apart from the swelling in the pharyngeal region there is not uncommonly marked lymphadenitis on both sides of the neck; this is often accompanied by œdema and even in some cases by an acute inflammation of the subcutaneous tissues of the neck; the result may then be pressure on the trachea, an exceptional indication for operation. It is necessary to lay stress on the fact that the obstruction is usually extremely slight and that *a priori* there might seem little hope of material benefit from operation. It would appear, however, that it is its duration, possibly extending to several days, which tells on the general condition and, especially, puts a strain on the heart.

2. *Restlessness.*—This is partly due to the difficult breathing; the patient is often delirious or semi-conscious and does not seem to realise that his respiration is laboured, yet he may appear obviously distressed. He often tosses about uneasily, pushes away the bed-clothes, and sometimes tries to sit up. He may be unable to sleep, sedatives having very little effect. The condition is, of course, one that must tell on the already toxin-weakened—perhaps partly asphyxiated—heart. The distress often increases considerably when the patient attempts to drink or during applications to the throat and nose. At such times there may be coughing, return of fluid through the nose, cyanosis, exhaustion so great that treatment has to be stopped, feeding by the mouth discontinued, and rectal feeding resorted to.

BRITISH ELECTRO-THERAPEUTIC SOCIETY.—The annual general meeting of this society will be held at 11, Chandos-street, Cavendish-square, W., to-day (Friday, Jan. 25th) at 8.30 P.M., when the election of officers of the society for 1907 will take place. Mr. J. Hall-Edwards, the retiring president, will deliver an address.

3. *Recession.*—There is sometimes recession of the epigastrium during inspiration, especially in very young children. It is then accompanied by retraction of the lower intercostal spaces, but it is never extreme as in cases of laryngeal diphtheria. Usually the recession is very slight or even absent. When it is not marked it can often be more easily appreciated by placing the hand on the lower part of the chest.

4. *Condition of the heart.*—The strain placed on the heart by the continued, although slight obstruction is the most important factor in the unfavourable drift of such cases. The heart responds for a time by over-action—often apparent when the hand is placed over the precordial region. But enfeebled and probably receiving insufficient oxygen it sooner or later begins to fail; the first sign noticed may be a slight diminution in the force of beat during inspiration—an interesting fact in view of the small degrees of obstruction. Thereafter, if the obstruction remains unrelieved the heart becomes gradually weaker and the patient dies from heart failure.

5. *Condition of the pulse.*—The pulse is at first full and rapid; it soon increases in rate and becomes weaker. This difference in volume may at first only be marked during inspiration, and in some cases there may even be a typical *pulsus paradoxus*—a sign of extreme gravity in the absence of surgical interference.

6. *Colour of the face.*—In most cases the colour is not much altered; there may be slight lividity about the mouth and nose; occasionally the lips are rather blue but definite cyanosis is rare.

7. *Septic laryngitis.*—In most cases more or less septic laryngitis is present but it seldom in itself calls for operation; in one case of the present series (Case 3) laryngeal symptoms with signs of obstruction developed at the end of the second week and were due to extension of the septic process to the larynx.

Apart from these cases, tracheotomy has been done in one or two instances for hæmorrhage from the naso-pharynx in which plugging of the posterior nares did not arrest the bleeding. The operation was done as a last resource and the bleeding checked by plugging the pharynx.

One weighty consideration in favour of operation is that the drift of the case is towards death. The improvement within a few hours, especially in the cardiac condition, is remarkable, and this is true even of cases which ultimately die from the general severity of the attack. Considering the severity of the cases, it is to be expected that in spite of temporary improvement death will sometimes occur.

OPERATION.

In spite of the marked improvement these cases show after tracheotomy there are certain points which should be considered before it is undertaken, as owing to the exhausted state of the patient a special element of danger enters into it.

1. *Anæsthetic.*—The question of the anæsthetic is often a serious one. The patients are usually in such an exhausted condition that very little of any anæsthetic should be given. Often it will be better to operate under local anæsthesia; if a general anæsthetic is used, ethyl chloride is in my experience satisfactory.

2. *Condition of the neck.*—Owing to the swelling and œdema of the tissues of the neck the operation may be a little more difficult; the trachea will not be so easily felt, especially in young and fat children.

3. *Hæmorrhage.*—This is the principal danger of the operation. In septic conditions there is always a certain tendency to bleeding; there may be more or less epistaxis, the lips and mouth become ulcerated and bleed easily, and if a wound is made oozing tends to continue even when all vessels of any size are tied; forcible pressure therefore is, as a rule, inefficient. The only resource is to plug the wound tightly around the tube. Adrenalin may be used if necessary but should be avoided if possible; it has been thought lately that in a few cases in which it had been used it increased the dryness of the trachea below the tube and gave rise to considerable trouble during the after-treatment. Styptics which coagulate blood should also be avoided, as they may induce clotting of the blood inside the trachea; fatal obstruction has resulted.

4. *Method.*—The usual method of operation in this hospital for cases of laryngeal diphtheria is the high rapid tracheotomy done with a small incision. It is performed in two steps: one downward incision through the skin and subcutaneous

tissues and one upwards through the upper two or three rings of the trachea. No stitches or ligatures are necessary in ordinary cases, as there is, as a rule, very little bleeding. This is the method generally used in the cases under consideration, and in these when troublesome oozing occurs it may be advisable to enlarge the wound and seek for bleeding points, but experience shows that such bleeding is nearly always controlled by plugging. The only cases in which the slow method with a long incision has a definite claim is when swelling and œdema of the neck make it difficult to incise and enter the trachea.

5. *Tubes.*—Parker's tubes are usually employed; Durham's lobster tail tubes are, however, very serviceable when there is much swelling, as the stem is longer and the moveable plate can be adapted to the neck. It is preferable to use as large a tube as possible (i.e., a No. 3 Parker for a child of two years); the advantage is that a wide tube will not get blocked so easily with the profuse thick mucus which is coughed through it. The length of time that the tube will have to be worn varies, but it is better to leave it until the throat is quite clean and no discharge passes through it. The outer tube is taken out once or twice a day to be sterilised and if it cannot be dispensed with by the fifth morning a rubber tube is substituted.

EFFECTS OF THE OPERATION.

Almost at once restlessness diminishes, respiration becomes quite free, and the patient tends to sleep. The pulse also shows definite—often very striking—improvement. A fall of temperature within the first few hours is common; it is often followed by a rise and the temperature may then be even higher than before the operation, but it usually comes down within three days. This immediate post-operative fall of temperature was noticed in seven cases of the present series. One marked advantage of the operation is that afterwards the treatment of the nose and throat is very much facilitated. The throat may be swabbed and the nose sprayed without causing any distress or discomfort to the patient.

The following is a brief history of 15 cases which were admitted into Plaistow Hospital. They were cases of septic scarlet fever or mixed cases—i.e., scarlet fever and diphtheria.

CASE 1.—A girl, aged 21 years, was admitted on Feb. 20th, 1903, with scarlet fever and diphtheria. There was some sloughy membrane on both tonsils and also one or two yellowish white spots were present on the posterior pharyngeal wall; the pharynx was intensely congested and very adenomatous. A profuse generalised scarlatinal rash was present. The temperature was 103° F., the pulse was 130, and the respirations were 25. During the first days there was a steady increase of difficulty in the breathing. The patient was almost continuously delirious and took food very unwillingly. Albuminuria appeared and lasted until the end of the fourth week. An abscess formed on the right side of the neck and profuse nasal discharge was present. The temperature remained high, reaching once to 104° F. On the seventh day there was much respiratory distress; the respirations reached 40 and the pulse was much more rapid and feeble. Breathing was noisy and inspiration in particular was laboured; evidently there was constant strain on the chest walls. The patient was in fact steadily losing ground from the slight respiratory obstruction and went to rest which sedatives failed to give. Throughout the seventh day she was only partially conscious and by the evening had sunk into a deep stupor. There was some lividity of the lips and the extremities. As a result of tracheotomy, breathing became obviously easier and within a few minutes some improvement was appreciable in the pulse. This improvement continued through the night and on the next morning the patient was conscious. Some membrane and much thick mucus were coughed up through the tube during the first few days. Five days after the operation the temperature was normal and the tube was removed. In all, 103,000 units of antitoxin were given subcutaneously in four doses. The patient remained enfeebled for many months, but eventually she completely recovered.

Remarks.—The degree of obstruction in this case was far less than that which ordinarily determines tracheotomy and the operation was only undertaken as a last resource in an apparently hopeless case. The total dose of antitoxin given was very large, the case having occurred at a time when maximum doses were used for severe laryngeal cases and also in mixed cases. The antitoxin was given on the mere probability that the larynx and the passages beyond might be involved in the diphtherial process. As already stated, this diagnosis proved correct.

CASE 2.—A boy, aged one year, was admitted with scarlet fever and diphtheria on April 6th, 1904, on what was said to be the second day of the disease. There was a slight rash on the body and the pharynx was very congested. The tonsils were covered with membrane. There was profuse discharge from the nose and adenitis was present on both sides of the neck. The temperature was 102° F., the pulse was 168, and the respirations were 44. 20,000 units of antitoxin were injected subcutaneously. On the third day the temperature rose to 105° and the respirations became more rapid. The child refused to be fed by the mouth and nasal feeds had to be resorted to, but it soon became impossible to pass the nasal catheter as it caused so much distress and

reactions go far, in the opinion of the writer of this paper, to render his theory worthy of consideration.

The radio-therapeutic technique, with radiosometric chart, I propose submitting in due course to *Medical Electrology and Radiology*, in the October number of which journal a significant article from the pen of Dr. H. B. Wilkinson, physician in charge of the San Lazaro Hospital, Manila, appears in an abstract, under the title "The Treatment of Leprosy with the X Rays," to which I would direct the attention of those interested in advanced therapeutics. Of this I will quote one sentence: "Another case was well after 14 treatments. The writer is inclined to believe that when a local lesion of leprosy is treated with the x rays the organisms there localised are killed, and their bodies are absorbed into the system, thereby producing an immunity of the system against the living organisms."

Holzknacht says: "The cure of an infective process is not due to any bactericidal action of the x rays, since the bactericidal dose is many times as great as the curative dose." This theory in regard to the mechanism of x rays is quite compatible with the theory of the parasitic origin of cancer. "Skinner has given a detailed *résumé* of the hypotheses put forward to explain the cure of malignant tumours by the x rays. According to the third hypothesis cancer is a parasitic disease, and the x rays destroy or hinder the development of the parasites. It may be, however, that the x rays are not destructive to the parasite itself, but in some way modify the tissues so as to prevent its development."

In this reference, Dr. G. H. A. Clowes of the New York State Cancer Laboratory, in his article entitled "A Study of the Influence exerted by a Variety of Physical and Chemical Forces on the Virulence of Carcinoma in Mice" states: "That immune forces are produced in the serum in gradually increasing quantities as the tumour progresses is indicated by the tendency frequently exhibited by tumours to remain stationary, after fairly rapid development, and then subsequently either to grow rapidly or retrogress. In this connexion it must be noted that x rays produce a much more marked effect at this stage, at which apparently the tumour (?) has quite overcome the natural immunity of the mouse, and is developing rapidly."

Dr. Belot thus sums up: "In conclusion, we may say that the x rays exercise a special action on certain cancerous cells, causing their degeneration and absorption, but that the mechanism of the action is still unknown."

I am tempted by the obvious therapeutic parallelism in the recently reputed medicinal agents in cancer to enter into their probable therapeutic values as recorded in the experience of others. I refer to papain, trypsin, and amylopsin, but I will only add that these enzymes, when injected in emulsion into the encapsulating tissues where metabolism has come to a standstill, bring about active resolution (if veins are avoided) by virtue of their proteolytic and diastatic properties on those tissues, when the lesions are accessible and not too deeply situated. They may thus liberate the vaccine when present in the lymphatic glands with the desired result if they do not influence it unfavourably by admixture before neutralisation.

Clinical experience is greatly in advance of the theories hitherto put forward, and I am not in a position at present to make manifest the above theory "by columns of figures and percentages of calculations of cures." I merely venture to submit these observations in the hope that if confirmed by those who have the necessary facilities for working in this department of therapeutics they will afford a solid basis for the scientific employment of radiotherapy, as well as for the proper classification of those conditions in which its use is indicated, and a most important field of medication will thus be opened up among those chronic ailments which occur after middle life and in which ordinary therapeutic measures have so far failed.

TRACHEOTOMY IN SLIGHT RESPIRATORY OBSTRUCTION ASSOCIATED WITH FEBRILE TOXÆMIA.

By A. O. BISSON, M.R.O.S. ENG., L.R.C.P. LOND.,
JUNIOR ASSISTANT MEDICAL OFFICER, PLAISTOW FEVER HOSPITAL.

IN fever practice there is a type of case occasionally encountered in which toxæmia is accompanied by very slight—apparently inconsiderable—obstruction of respiration. Cases of this kind are perhaps commonest in septic scarlet fever with swelling in the faucial region and the naso-pharynx, possibly with some degree of septic laryngitis. A somewhat similar condition, however, is now and then seen in small-pox; one case of this type occurred at Dagenham Hospital during the last epidemic in London. The laryngitis caused a slight degree of obstruction which, owing to the enfeebled state of the patient, soon began to tell on his cardiac condition. Tracheotomy was performed; it was followed by a remarkable improvement and the patient recovered. There is also a septic type of diphtheria defined by Monti in which the larynx is but little affected; there is slight obstruction but it is not progressive and the patient apparently goes downhill as a result of the toxæmia alone. Some years ago, in a case at Plaistow Hospital, the question arose whether the patient's steady loss of ground might not be in part the result of very slight respiratory obstruction—strain on the respiratory muscles and deficiency of oxygen. The result of tracheotomy was a striking improvement in the condition of the patient with ultimate recovery where it seemed hardly possible. In consequence of this result it was laid down as a principle that no patient with slight respiratory obstruction should be allowed to die without tracheotomy having been resorted to. From time to time such cases have occurred at Plaistow Hospital; some of them have been under my care, and it may be of service in calling attention to a procedure so far not emphasised in medical literature. Its importance cannot be measured by the frequency of the cases in which it applies, because when such cases do occur they are of a grave nature, and the operation, as I hope to show, is sometimes life-saving.

INDICATIONS FOR OPERATION.

The indications for tracheotomy in the type of case under consideration are:—

1. *Difficult breathing.*—Owing to the intense congestion of the fauces and the profuse muco-purulent discharge from the naso-pharynx insufficient air reaches the lungs. The patient may breathe with the mouth open and the lower jaw often drops during each inspiration. The breathing is noisy owing to gurgling of the accumulated discharge in the pharynx, stridor being seldom present. The respirations are usually increased in frequency and the *alae nasi* are brought into action; this increase in frequency is not marked and as in definite laryngeal obstruction the respirations may be slower than one might expect from the height of the temperature and the rapidity of the pulse. Apart from the swelling in the pharyngeal region there is not uncommonly marked lymphadenitis on both sides of the neck; this is often accompanied by oedema and even in some cases by an acute inflammation of the subcutaneous tissues of the neck; the result may then be pressure on the trachea, an exceptional indication for operation. It is necessary to lay stress on the fact that the obstruction is usually extremely slight and that *a priori* there might seem little hope of material benefit from operation. It would appear, however, that it is its duration, possibly extending to several days, which tells on the general condition and, especially, puts a strain on the heart.

2. *Restlessness.*—This is partly due to the difficult breathing; the patient is often delirious or semi-conscious and does not seem to realise that his respiration is laboured, yet he may appear obviously distressed. He often tosses about uneasily, pushes away the bed-clothes, and sometimes tries to sit up. He may be unable to sleep, sedatives having very little effect. The condition is, of course, one that must tell on the already toxin-weakened—perhaps partly asphyxiated—heart. The distress often increases considerably when the patient attempts to drink or during applications to the throat and nose. At such times there may be coughing, return of fluid through the nose, cyanosis, exhaustion so great that treatment has to be stopped, feeding by the mouth discontinued, and rectal feeding resorted to.

BRITISH ELECTRO-THERAPEUTIC SOCIETY.—The annual general meeting of this society will be held at 11, Chandos-street, Cavendish-square, W., to-day (Friday, Jan. 25th) at 8.30 p.m., when the election of officers of the society for 1907 will take place. Mr. J. Hall-Edwards, the retiring president, will deliver an address.

3. *Recession.*—There is sometimes recession of the epigastrium during inspiration, especially in very young children. It is then accompanied by retraction of the lower intercostal spaces, but it is never extreme as in cases of laryngeal diphtheria. Usually the recession is very slight or even absent. When it is not marked it can often be more easily appreciated by placing the hand on the lower part of the chest.

4. *Condition of the heart.*—The strain placed on the heart by the continued, although slight obstruction is the most important factor in the unfavourable drift of such cases. The heart responds for a time by over-action—often apparent when the hand is placed over the precordial region. But enfeebled and probably receiving insufficient oxygen it sooner or later begins to fail; the first sign noticed may be a slight diminution in the force of beat during inspiration—an interesting fact in view of the small degrees of obstruction. Thereafter, if the obstruction remains unrelieved the heart becomes gradually weaker and the patient dies from heart failure.

5. *Condition of the pulse.*—The pulse is at first full and rapid; it soon increases in rate and becomes weaker. This difference in volume may at first only be marked during inspiration, and in some cases there may even be a typical pulsus paradoxus—a sign of extreme gravity in the absence of surgical interference.

6. *Colour of the face.*—In most cases the colour is not much altered; there may be slight lividity about the mouth and nose; occasionally the lips are rather blue but definite cyanosis is rare.

7. *Septic laryngitis.*—In most cases more or less septic laryngitis is present but it seldom in itself calls for operation; in one case of the present series (Case 3) laryngeal symptoms with signs of obstruction developed at the end of the second week and were due to extension of the septic process to the larynx.

Apart from these cases, tracheotomy has been done in one or two instances for hæmorrhage from the naso-pharynx in which plugging of the posterior nares did not arrest the bleeding. The operation was done as a last resource and the bleeding checked by plugging the pharynx.

One weighty consideration in favour of operation is that the drift of the case is towards death. The improvement within a few hours, especially in the cardiac condition, is remarkable, and this is true even of cases which ultimately die from the general severity of the attack. Considering the severity of the cases, it is to be expected that in spite of temporary improvement death will sometimes occur.

OPERATION.

In spite of the marked improvement these cases show after tracheotomy there are certain points which should be considered before it is undertaken, as owing to the exhausted state of the patient a special element of danger enters into it.

1. *Anæsthetic.*—The question of the anæsthetic is often a serious one. The patients are usually in such an exhausted condition that very little of any anæsthetic should be given. Often it will be better to operate under local anæsthesia; if a general anæsthetic is used, ethyl chloride is in my experience satisfactory.

2. *Condition of the neck.*—Owing to the swelling and œdema of the tissues of the neck the operation may be a little more difficult; the trachea will not be so easily felt, especially in young and fat children.

3. *Hæmorrhage.*—This is the principal danger of the operation. In septic conditions there is always a certain tendency to bleeding; there may be more or less epistaxis, the lips and mouth become ulcerated and bleed easily, and if a wound is made oozing tends to continue even when all vessels of any size are tied; forcible pressure therefore is, as a rule, inefficient. The only resource is to plug the wound tightly around the tube. Adrenalin may be used if necessary but should be avoided if possible; it has been thought lately that in a few cases in which it had been used it increased the dryness of the trachea below the tube and gave rise to considerable trouble during the after-treatment. Styptics which coagulate blood should also be avoided, as they may induce clotting of the blood inside the trachea; fatal obstruction has resulted.

4. *Method.*—The usual method of operation in this hospital for cases of laryngeal diphtheria is the high rapid tracheotomy done with a small incision. It is performed in two steps: one downward incision through the skin and subcutaneous

tissues and one upwards through the upper two or three rings of the trachea. No stitches or ligatures are necessary in ordinary cases, as there is, as a rule, very little bleeding. This is the method generally used in the cases under consideration, and in these when troublesome oozing occurs it may be advisable to enlarge the wound and seek for bleeding points, but experience shows that such bleeding is nearly always controlled by plugging. The only cases in which the slow method with a long incision has a definite claim is when swelling and œdema of the neck make it difficult to incise and enter the trachea.

5. *Tubes.*—Parker's tubes are usually employed; Durham's lobster tail tubes are, however, very serviceable when there is much swelling, as the stem is longer and the moveable plate can be adapted to the neck. It is preferable to use as large a tube as possible (i.e., a No. 3 Parker for a child of two years); the advantage is that a wide tube will not get blocked so easily with the profuse thick mucus which is coughed through it. The length of time that the tube will have to be worn varies, but it is better to leave it until the throat is quite clean and no discharge passes through it. The outer tube is taken out once or twice a day to be sterilised and if it cannot be dispensed with by the fifth morning a rubber tube is substituted.

EFFECTS OF THE OPERATION.

Almost at once restlessness diminishes, respiration becomes quite free, and the patient tends to sleep. The pulse also shows definite—often very striking—improvement. A fall of temperature within the first few hours is common; it is often followed by a rise and the temperature may then be even higher than before the operation, but it usually comes down within three days. This immediate post-operative fall of temperature was noticed in seven cases of the present series. One marked advantage of the operation is that afterwards the treatment of the nose and throat is very much facilitated. The throat may be swabbed and the nose sprayed without causing any distress or discomfort to the patient.

The following is a brief history of 15 cases which were admitted into Plaistow Hospital. They were cases of septic scarlet fever or mixed cases—i.e., scarlet fever and diphtheria.

CASE 1.—A girl, aged 21 years, was admitted on Feb. 20th, 1903, with scarlet fever and diphtheria. There was some sloughy membrane on both tonsils and also one or two yellowish white spots were present on the posterior pharyngeal wall; the pharynx was intensely congested and very œdematous. A profuse generalised scarlatinal rash was present. The temperature was 103° F., the pulse was 130, and the respirations were 24. During the first days there was a steady increase of difficulty in the breathing. The patient was almost continuously delirious and took food very unwillingly. Albuminuria appeared and lasted until the end of the fourth week. An abscess formed on the right side of the neck and profuse nasal discharge was present. The temperature remained high, reaching once to 104° 4". On the seventh day there was much respiratory distress; the respirations reached 40 and the pulse was much more rapid and feeble. Breathing was noisy and inspiration in particular was laboured; evidently there was constant strain on the chest walls. The patient was in fact steadily losing ground from the slight respiratory obstruction and want of rest which sedatives failed to give. Throughout the seventh day she was only partially conscious and by the evening had sunk into a deep stupor. There was some lividity of the lips and the extremities. As a result of tracheotomy, breathing became obviously easier and within a few minutes some improvement was appreciable in the pulse. This improvement continued through the night and on the next morning the patient was conscious. Some membrane and much thick mucus were coughed up through the tube during the first few days. Five days after the operation the temperature was normal and the tube was removed. In all, 102,000 units of antitoxin were given subcutaneously in four doses. The patient remained enfeebled for many months, but eventually she completely recovered.

Remarks.—The degree of obstruction in this case was far less than that which ordinarily determines tracheotomy and the operation was only undertaken as a last resource in an apparently hopeless case. The total dose of antitoxin given was very large, the case having occurred at a time when maximum doses were used for severe laryngeal cases and also in mixed cases. The antitoxin was given on the mere probability that the larynx and the passages beyond might be involved in the diphtherial process. As already stated, this diagnosis proved correct.

CASE 2.—A boy, aged one year, was admitted with scarlet fever and diphtheria on April 6th, 1903, on what was said to be the second day of the disease. There was a slight rash on the body and the pharynx was very congested. The tonsils were covered with membrane. There was profuse discharge from the nose and adenitis was present on both sides of the neck. The temperature was 102° 8° F., the pulse was 168, and the respirations were 44. 20,000 units of antitoxin were injected subcutaneously. On the third day the temperature rose to 105° and the respirations became more rapid. The child refused to be fed by the mouth and nasal feeds had to be resorted to, but it soon became impossible to pass the nasal catheter as it caused so much distress and

the child had to be fed by the rectum. On the sixth day the breathing was more laboured, there was slight recession, and the pulse was more rapid and softer. Tracheotomy was performed. Immediately afterwards the respirations became slower and easier and the temperature came down from 103.8 to 100.6°; it rose again, however, to 114.4° before death, which occurred 13 hours after the operation.

CASE 3.—A boy, aged four years, was admitted with scarlet fever on April 27th, 1904, on the fifth day of the disease. On admission the body was covered with a characteristic rash; the tonsils were swollen and covered with a thin yellowish exudate but there was no nasal discharge. The temperature was 103° F., the pulse was 136 and the respirations were 38. The condition of the throat improved slightly during the first few days, but on May 10th a laryngeal cough and stridor developed. The possibility of membranous croup was practically excluded as the child had received a prophylactic dose of antitoxin on the day of admission. The obstruction was only slight, but as it was beginning to tell on the general condition of the child intubation was tried; only partial relief followed and tracheotomy had to be done. It was evident that the obstruction was due to septic laryngitis; the relief which followed the operation was complete. The tube was removed on the third day and the child was quite comfortable without it, but as the wound began to close the distress returned and four days later the wound had to be reopened and a rubber tube inserted. This tube had to be worn for several weeks and each time it was removed the child became very distressed. His condition improved very much until June 6th when signs of pleuro-pneumonia on the left side of the chest appeared. Ten ounces of fluid were aspirated on the following day, but it collected again and became purulent. The empyema was opened and drained on June 10th. The child slowly recovered from this complication and when strong enough was allowed to get up. He was then still wearing his rubber tracheotomy tube. On Sept. 16th it was removed and the child was intubated with a No. 1 metal tube; this one was worn until Sept. 25th; it was removed every fourth day for cleaning purposes and replaced. On the 26th a No. 2 tube was inserted and was worn until Oct. 9th. Between that day and the 16th the tube was repeatedly coughed up, on one occasion three times in half an hour, and as each time the child could not breathe comfortably for more than a few minutes a second tracheotomy was performed on the 16th. During the time that he was intubated he was able to take solid food by the mouth but fluids had to be given with the nasal catheter. On Nov. 3rd the child contracted diphtheria; it attacked the tracheotomy wound, involved the trachea, and rapidly spread to the bronchi. The patient died on Nov. 11th.

Remarks.—This case unfortunately ended fatally but it is interesting for several reasons. It is highly probable that the child would have died soon after admission if the first tracheotomy had not been performed; the septic laryngitis undoubtedly caused some deep ulceration which later led to cicatricial stenosis and required a secondary intubation. The repeated intubations dilated the stenosis up to a certain point but may have caused recurrence of the ulceration, as repeated coughing up of the tube indicates this condition. Finally, the diphtherial process involved the tracheotomy wound, a rare occurrence since antitoxin has been used. In this case 40,000 units were given intravenously.

CASE 4.—A boy, aged five years, was admitted on Sept. 26th, 1904, with scarlet fever. There was a history of sore-throat and headache since the 24th; the rash appeared on the 25th. On admission the child was delirious and the body was covered with a profuse scarlatinal rash. There was no rhinorrhoea but the pharynx was covered with thick muco-pus. The temperature was 104.2° F. and the pulse was 140. The respirations were 32 but there was then no marked difficulty in the breathing. On the 28th the child complained of headache and carache and the neck became swollen. During the first few days the condition of the throat improved slightly and there was less fever, but the general condition again grew worse and on Oct. 8th the child had some epistaxis and nasal discharge. On the 8th the temperature was again 104° and the restlessness increased; there was more discharge from the nose and throat and signs of double otitis media developed. On the 11th the swelling of the cervical glands had increased and the breathing was very distressed; the pulse was 160 and weaker. On the 12th the child vomited several times, albuminuria appeared, and the respirations became more laboured. Tracheotomy was performed on the 13th and was followed by complete relief of the breathing. The pulse improved markedly soon after the operation; it was slower (132) and stronger 12 hours later the temperature had come down from 103.6° to 100.8°. For several days the state of the throat remained unchanged and there was profuse offensive discharge from the nose, but the treatment was made much easier after the tracheotomy. On the 18th a patch of necrotic tissue was present on the right tonsil and part of the soft palate, and on the 21st there was profuse salivation, the saliva being blood-stained. During the following night the slough separated and there was hæmorrhage from a deep wound in the soft palate; blood was lost to the amount of about six ounces. All treatment of the nose and throat was discontinued, also the nasal feeds which had been given since tracheotomy; the child was now fed per rectum. The bleeding was checked by pressing pieces of ice into the ulcerated cavity and holding them there with the finger. There was no recurrence of the hæmorrhage and 24 hours later the nasal feeds were resumed. The patient remained in a critical condition for several days, fever persisting until Nov. 4th. On the 7th the tracheotomy tube was permanently removed; there was still some regurgitation of fluids through the nose owing to loss of part of the soft palate, and the child had to be nasal-fed several weeks, but eventually was able to take all food by the mouth. He was discharged quite well on Dec. 5th. His voice has remained nasal ever since.

Remarks.—In this case the operation served a double purpose: it not only relieved the respiratory obstruction but made it possible to deal with the hæmorrhage efficiently and so probably saved the patient's life.

CASE 5.—A boy, aged one year, was admitted with scarlet fever on Dec. 26th, 1904, on the eighth day of the disease. On admission the rash was still evident on the body, the throat was swollen, and a thin grey exudate covered the uvula, the tonsils, and part of the soft palate. The temperature was 102.4° F. and the pulse was 132. The respirations were 32. The condition remained unchanged until the 23rd; on that day there was more discharge from the throat, rhinorrhoea appeared, and the glands of the neck began to swell. The child was given 20 cubic centimetres of antistreptococcal serum intravenously and 10 cubic centimetres subcutaneously. On the 30th the respirations were more rapid and laboured and there was some recession. The temperature was 103.4°, the pulse was 145, and the respirations had increased to 40. Tracheotomy was performed and soon afterwards a great deal of muco-pus was coughed up through the tube and the respirations were relieved for a time. The discharge, however, became very thick and frequently blocked the tube; this each time caused recurrence of the distress and the tube had often to be removed and cleaned during the first two days which followed the operation. The heart gradually became weaker, the temperature went on rising, and remained between 104° and 105° until death, which occurred on Jan. 2nd, from broncho-pneumonia.

CASE 6.—A boy, aged five years, was admitted with scarlet fever on April 26th, 1905. The history was that on the 21st he had severe vomiting, sore throat, carache, and nasal discharge. The rash appeared on the 22nd. On admission the patient was moribund, he was unconscious, his breathing was laboured, and he had some recession. The temperature was 103.8° F., the pulse was 124 and very small, and the respirations were 62. There was considerable swelling in the faucal region; the tonsils were so swollen and the soft palate was so oedematous that the fauces were almost completely occluded. There was profuse discharge from the nose and throat and the cervical glands were moderately enlarged. The right ear was also discharging. The case appeared beyond the reach of any non-operative treatment. Tracheotomy was done under local anaesthesia about an hour after admission and the child was at once able to breathe more comfortably; a great deal of offensive mucus was coughed up through the wound and the respirations came down to 42. The child was placed in steam. From the appearance of the throat a diphtherial element was suspected (although a subsequent cultivation only showed streptococci) and 10,000 units of antitoxin, with 25 cubic centimetres of antistreptococcal serum were injected intravenously by direct puncture. 15 hours later the temperature had come down from 103.6° to 101°, but the heart was so weak that heart failure seemed imminent; stimulants were freely given and the pulse improved slightly. On the 23rd the tube was removed but the patient was still kept in steam for three days longer. Albuminuria appeared and there was almost complete anuria for two days. For the first 36 hours after the operation the child was fed by the rectum in case the use of the nasal tube should embarrass respiration. Nasal feeding was then employed and was continued until the tracheotomy wound had completely healed. As local treatment formalin was applied to the throat with a cotton-wool swab. The cervical glands continued to enlarge during the first few days but they gradually subsided and on May 2nd they could just be felt and the throat was almost clean. Thenceforward the child improved slowly. Left otitis media developed during the second week and an abscess on the left side of the neck during the fifth week. He was discharged quite well at the end of the eleventh week.

CASE 7.—A girl, aged six years, was admitted with scarlet fever on May 24th, 1905, on the sixth day of the disease. On admission the rash had faded but the nose was discharging freely; the throat appeared very septic and there was some salivation. The temperature was 103.8° F. and the child looked drowsy. During the first week she did not improve. The temperature remained high. Food was taken very unwillingly. The glands of the neck began to swell and signs of double otitis media developed. At the beginning of the second week there was slight improvement. The temperature came down one or two degrees and the child appeared more comfortable, but towards the end of the week profuse hæmorrhage from the nose and throat occurred. It was checked by plugging the posterior nares and by spraying the throat with bazeine. She was weaker and more restless. The temperature was again 103°. A septic rash appeared all over the body and there was some diarrhoea with blood in the stools. Rectal feeds had to be given for three days as she would not take food by the mouth and the nasal catheter could not be passed owing to the danger of further hæmorrhage. There was partial suppression of urine. During the third week the condition was the same, except that the patient appeared weaker. She often talked in her sleep and was very restless when awake. The throat, nose, and ears showed no sign of improvement. During the fourth week the breathing became noisy and she often coughed. Some ulcerative stomatitis was present. Two teeth became loose and gangrenous areas developed around them. The teeth were removed and the patches were touched with liquefied carbolic acid. On June 17th the restlessness increased. At times there was also swollen and the breathing was distressed. Tracheotomy was performed as a last resource and was beneficial in relieving the respiratory obstruction and the restlessness. In spite of it the child slowly grew worse, the gangrenous process in the mouth spread, and more teeth had to be removed. The mouth was treated with chromic acid, but the gangrene extended to the lower lip and the chin, partly destroying the soft tissues. Some hæmorrhage from the mouth recurred at intervals during the fifth week. The child died from toxæmia on June 30th.

CASE 8.—A boy, aged three years, was admitted with scarlet fever on Sept. 13th, 1905, on the ninth day of the disease. No rash was present. The temperature was 101.5° F., the respirations were 36, and the pulse was 140 and of low tension. The lips and tongue were ulcerated and bled easily. The throat was congested and covered with muco-pus and the glands of the neck were very swollen, chiefly on the left side. The heart sounds were clear but weak and there was a slight cough but no physical signs in the lungs. The child had to be nasal-fed partly owing to regurgitation of fluids through the nose and partly because he refused to take nourishment by the mouth. On the 15th the general condition was the same and 20 cubic centimetres of antistreptococcal serum were injected intravenously. There were no respirations became more rapid (40) and distressed. There was slight recession and croupy cough. The child was put in steam with slight recession and croupy cough, however, the recession and restlessness gave some relief. A few hours later, however, the recession and restlessness increased, the pulse became more rapid and weaker (chiefly during inspiration), and tracheotomy was performed under local anaesthesia.

The respirations remained rapid but became quite free and the patient was able to sleep. No membrane was coughed through the tube. On the 17th the naso-pharynx was so swollen that the nasal catheter could not be passed and he had to be rectal fed. There was right otitis media. The pulse became gradually weaker and the child died from heart failure 22 hours after the operation.

CASE 9.—A boy, aged nine years, was admitted on Oct. 31st, 1905, with scarlet fever. There was a history of 11 days' illness which began with vomiting, sore-throat, and profuse nasal discharge. On admission the child presented all the signs of a very septic case. There was profuse offensive discharge from the nose and ears, the glands of the neck were very swollen, and the throat was congested and covered with a thin exudate. Respiration was noisy and laboured and there was some recession. The temperature was 101.8° F. and the pulse was 120. The child was delirious and very restless. On Nov. 1st the recession increased, the colour of the face, which from the first had been greyish, became rather livid, and there was also cyanosis of the lips. He was more restless and it became evident from the nature of the pulse that he was going downhill rapidly. Tracheotomy was performed under local anaesthesia, the child being too weak for a general anaesthetic. It was followed by complete relief of respiration, although the rate remained rapid. Soon after the operation the temperature dropped from 102.2° to 99.6°. 12 hours later he appeared moribund and his pulse could scarcely be felt. He was given stimulants with slight improvement but for several days he had frequent attacks of collapse during which heart failure seemed imminent. On the 3rd he coughed up a great deal of thick, offensive mucus through the tube. He was put in steam. On the 4th the tube was permanently removed. On the 6th the throat was clearer, there was less discharge from the nose, and the cardiac condition had improved slightly but the temperature was 101.8°. On the 8th the temperature was normal and steady improvement set in. The child had nephritis during the tenth and eleventh weeks but after that he made an uninterrupted recovery. He was kept in the hospital on account of persistent ear discharge until the nineteenth week but eventually went home quite well on March 3rd, 1906.

CASE 10.—A boy, aged three years, was admitted on Nov. 18th, 1905, on the fifth day of illness. There was no rash on admission, but the throat was in a very septic condition. The swelling of the glands of the neck was extreme and there was profuse thick discharge from the nose. The child was very collapsed when he came in and his breathing was noisy but there was no recession. The general condition remained unchanged until 12 days later when the breathing became more laboured. The neck was more swollen and oedematous and presented a typical picture of the "bull neck." The pulse was very much worse. A deep abscess had formed on the right side of the neck; this was opened and tracheotomy was performed. The child was much more comfortable and his general condition began to improve. During the first few days he was in the hospital swallowing was practically impossible owing to the intense swelling in the faucial region. Nasal feeds were resorted to but could not always be given as the passage of the catheter was often impossible owing to the congested state of the naso-pharynx; on these occasions rectal feeds had to be given. The patient was able to breathe comfortably without the tube on the fifth day after the operation but when the wound began to close the distress returned and the tube had to be reinserted. It was permanently removed seven days later. 17 days after the operation the temperature was normal and from that time the throat began to improve slowly and the swelling of the neck gradually subsided. This case was complicated by double otitis media and the convalescence was very slow. The child was sent home quite well in the twenty-second week.

The following case was extremely severe and approached the "malignant type" which may kill in 36 or 48 hours.

CASE 11.—A boy, aged seven years, was admitted on March 15th, 1906, with scarlet fever. There was a history of two days' illness which began with sore throat and violent vomiting. On admission the temperature was 100° F. but soon rose to 103° and remained between 103° and 104° until death. The pulse was 120 and small and the respirations were 45. There was profuse offensive discharge from the nose and ears. The throat was very congested. The tonsils were swollen. The soft palate was very oedematous. The tongue was thickly furled and could only be protruded with difficulty. Both sides of the neck were markedly swollen. The rash was intense and in places almost petechial; it only partly disappeared on pressure and covered the whole body. During the first two days the condition grew steadily worse; the child vomited at frequent intervals and owing to the condition of the naso-pharynx the breathing became very difficult. The patient tended from time to time to become cold but no rigor occurred. He was almost unconscious and very restless. On the morning of the third day the respirations had become very laboured and the pulse was much weaker; there was also indrawing of the lower part of the chest during inspiration. Tracheotomy was performed under local anaesthesia and completely relieved the distress. The child became very quiet but the pulse grew weaker and death occurred three hours later.

Remarks.—In this case the relief following the operation was so striking that it was deeply regretted that it had not been done soon after admission. However, owing to the profound toxæmia present, it is doubtful whether an early operation would have altered the prognosis but it would certainly have relieved the respiratory distress and restlessness and very much facilitated the nursing of the case.

CASE 12.—A boy, aged two years, was admitted with scarlet fever on March 23rd, 1906, the seventh day of the disease. On admission a scarlatinal rash was still present on the abdomen and limbs. Both sides of the neck were swollen and there was an abundant mucopurulent discharge from the nose. Respiration was rapid and difficult, the pulse was 145, and the temperature was 103° F. It was stated that the breathing had been laboured during the two days before admission. The temperature remained high (between 103° and 104°) for the first 35 hours. Meanwhile the respiratory distress steadily increased, the pulse grew weaker, and some recession appeared. Tracheotomy was performed on the 25th. Troublesome bleeding occurred and could not be stopped by force-pressure, as it was a general oozing characteristic of

these septic cases; it was only controlled by plugging the wound slightly around the tube. The breathing was relieved and the temperature dropped from 103.2° to 99.8°. As much thick mucus was being coughed up through the tube the child was put in steam. On the 27th the temperature was still high and the swelling of the neck had increased; it was more brawny and had extended upwards towards the scalp. On the 28th there was diffuse cellulitis of the neck and scalp. The tracheotomy wound was looking quite clean at the time of death, which occurred on that day from toxæmia.

CASE 13.—A boy, aged 11 years, was admitted with scarlet fever and diphtheria on Sept. 2nd, 1903, on the sixth day of the disease. On admission a profuse bright scarlatinal rash covered the whole body. The throat was very swollen and oedematous and there was some dirty-looking membrane on one tonsil. The posterior wall of the pharynx was almost completely hidden by the swelling of the faucial regions; what could be seen of it was covered with thick mucopus. The cervical glands were very swollen and there was a great deal of offensive discharge from the nose. The tongue and lips were ulcerated and bled readily. The child was delirious; he refused to take his food and constantly tried to sit up in bed. The temperature was 103° P., the pulse was 144, and the respirations were 40. He was given 50,000 units of antitoxin and 20 cubic centimetres of antistreptococcal serum subcutaneously. During the evening the restlessness increased, breathing became very laboured, and there was slight recession during inspiration. The pulse was more rapid (160) and weaker. Tracheotomy was performed at 1 o'clock the next morning and was followed by a striking improvement. The patient was able to sleep all night, his respirations became quite free, and his pulse stronger and slower (135). There was considerable hæmorrhage at the time of the operation but it was controlled by plugging the wound and did not recur. During the following days pieces of membrane and much mucopus were coughed up through the tube. The throat remained in the same state for several days. On the 12th the throat was clean and the tube was removed. On the 16th right otitis media developed. There was some ear discharge for four weeks and the child was sent home quite well in the ninth week.

CASE 14.—A boy, aged two years, was admitted with scarlet fever and diphtheria on Oct. 12th, 1906 with a history of four days' illness. On admission a bright rash covered the body and limbs. The throat was congested and some membrane was present on both tonsils and the soft palate. There was some lymphadenitis on both sides of the neck. The temperature was 102.6° F., the pulse was 135, and the respirations were 44. The heart sounds were clear but weak. Antitoxin (25,000 units) and antistreptococcal serum (20 cubic centimetres) were injected subcutaneously. On the evening of the 13th the child became more restless and there was a slight cough which at times sounded croupy. The pulse went up to 160 with no corresponding increase of the temperature and it was very weak. Some recession was present and the child looked distressed although the colour was good. From the condition of the pulse it was evident that the heart was feeling the strain of the obstruction. Tracheotomy was performed and as soon as the trachea was opened several large pieces of membrane were coughed up. For a time the child breathed quite easily but on the evening of the 14th signs of broncho-pneumonia developed. More antitoxin (50,000 units) were given and the child was put in steam. On the 15th there was some cyanosis. Inhalations of oxygen were tried and gave great relief, but only for a short time. The respirations became gradually more rapid and shallow and the patient died the same evening, 42 hours after the operation.

The following case was not operated on for obstruction but for uncontrollable hæmorrhage from the naso-pharynx.

CASE 15.—A girl, aged six years, was admitted on Dec. 28th, 1904, with scarlet fever. On admission the rash was still present on the body, there was profuse mucopurulent discharge from the nose and pharynx, and the tonsils were covered with thick cheesy exudate. During the first week the temperature remained above 103° F. and the general appearance was that of a very septic case. At the end of the second week profuse epistaxis occurred; plugging of the posterior nares was tried without success. As the child was getting collapsed tracheotomy was performed as a last resource and the pharynx was completely plugged; this efficiently controlled the bleeding. Troublesome hæmorrhage occurred from the wound and was only checked with difficulty. The patient died 12 hours later from toxæmia.

CONCLUSION.

In reviewing the cases described above it appears that in all of them the operation was beneficial; in the greater number the benefit proved only temporary but there were some in which, as far as could be judged, the patient's life was saved. Those who died were most of them very young and in children under three years the outlook is graver. Another factor which affects the prognosis is the time at which the operation is performed. On more than one occasion there has been reason to regret from the result of the operation that it was not done earlier.

In concluding I wish to acknowledge my indebtedness to Dr. J. Biernacki, medical superintendent of Plaiestow Hospital, for his kind permission to publish the cases described in this paper.

MILK-SUPPLY OF BRISTOL.—At the Bristol police court on Jan. 18th the chairman of the magistrates remarked, whilst fining a tradesman for selling milk containing 12.59 per cent. of added water, that the milk-supply in Bristol was disgraceful, for the annual report of the Local Government Board for 1905-06 showed that 457 samples were taken and 101 were found to be adulterated, whereas in Manchester 1260 samples were taken and only 83 were found to be adulterated.

THE GLANDULAR EXTRACT FROM IMMUNISED ANIMALS AS A CURATIVE AGENT IN PLAGUE.¹

BY S. MALLANNAH, M.D. EDIN., D.P.H. CANTAB.,
BACTERIOLOGIST TO THE GOVERNMENT OF M.H. THE NIZAM OF
HYDERABAD.

It is a well-known clinical fact that the cases of plague which generally recover are those in which the glandular reaction is most marked, whilst the most serious cases are those in which the glandular reaction is hardly observable. It is also observed in the laboratory that marked pathological changes occur in lymphatic glands, liver, and spleen, especially in those animals in which the disease from some cause or other runs a chronic course. I found, for example, marked necrotic changes in these organs in animals partially protected with Haffkine's fluid, and afterwards dying from plague when subsequently infected with the bacillus pestis. These facts induced me to consider that the organs on which the plague poison exercises its concentrated effect may probably be the centres where the antibodies are manufactured in great quantity in case of recovery. In this way I was led to consider whether it was possible to use some form of glandular extract from immunised animals as a curative agent in plague. In order to test the practicability of this theory I carried out some experiments in Hyderabad in the year 1900 and found that the glands of the immunised animals, such as the liver, the spleen, and the buboes when finely minced aseptically, and treated with absolute alcohol for two weeks or more and then allowed to dry at the room-temperature, could be easily converted into a fine powder. The powder thus obtained when well rubbed down in a sterile mortar with a sterile normal salt solution yielded on filtration a clear straw-coloured liquid which seemed to possess curative power when inoculated into animals artificially infected with a culture of the bacillus pestis. But as the number of experiments carried out was insufficient to form a definite opinion, and as I had no opportunities to carry out further experiments in Hyderabad, I dropped the subject and did not publish the results. Last September, through the kindness of Professor Dunbar, I was enabled to repeat these experiments at the Hygienic Institute, Hamburg, and the results so far obtained seemed to be very encouraging.

The method which I have used in preparing the curative powder from the glands of immunised animals is as follows: Healthy rabbits are inoculated with Haffkine's prophylactic fluid to produce slight immunity, just enough to give them a start. For this purpose I use the supernatant fluid after the sediment consisting of bodies of dead bacilli has thoroughly settled down, as I had shown some years ago² that the filtrate from Haffkine's fluid is quite as efficacious in producing immunity as are the entire contents thoroughly shaken up together as recommended by Haffkine, and has further the advantage of not producing local mischief, such as hard indurated swelling at the seat of injection containing sterile pus. Haffkine's fluid is given subcutaneously on two occasions with an interval of about 12 days between the injections, and when the animals have thoroughly recovered from its effects, say in from 10 to 12 days, they are subsequently inoculated with a very small quantity of a weak culture of living plague bacilli subcutaneously, and again after an interval of 10 or 12 days a larger dose of the weak culture is introduced. Subsequently a virulent germ is substituted for the weak one, commencing with the small doses and then gradually increasing the doses, always allowing an interval of about a fortnight between the injections for the animals to recover, till they can withstand the whole quantity of plague germs which will grow on a surface of an ordinary Petri dish. I continue these immunisations until at last the animals can withstand one or two loops of very virulent plague germs given intravenously. Lastly, the animals when quite sound are killed with chloroform, generally

15 days after the last intravenous injection, for the preparation of the powder. Microscopic examination of the juice of glands of such animals did not reveal the presence of any bacteria and no growth was obtained on the media inoculated. It is thus seen that the immunity in these animals is really produced by the living bacilli and is far higher than the immunity which could be produced by dead bacilli or their products. The production of such an immunity, however, is much more difficult, as one has to be very careful in graduating the doses so as to avoid killing the animals. I find that it generally takes from four to six months to produce such an immunity. After the animals have been killed with chloroform, the glands such as the liver, the spleen, the buboes, and the suprarenals are removed, are finely minced aseptically and spread in thin layers in sterile glass dishes, and are allowed to dry over sulphuric acid in a hot-air chamber at 47° C. for a period of from three to six days. When the material is thoroughly dried it is well ground in a sterile mortar to a fine powder, after which it is placed in small sterile flasks plugged with cotton-wool and replaced in a hot-air chamber for about 24 hours. The powder is now ready for use. It forms a brown cloudy emulsion when well rubbed down in a mortar with warm sterile water and can be easily injected into an animal with a needle of somewhat large calibre. I found that the process of drying the organs with alcohol takes a much longer time in Hamburg than in Hyderabad. I have therefore adopted Klein's³ method of drying the organs on account of the insufficiency of time at my disposal. I believe that the alcohol method and the use of larger animals would give better results.

The results of experiments with the gland powder thus prepared are given in a tabular form. Two strains of the bacillus pestis were used in the experiments, "Blagdon" and "Bishopsgate." The virulence of the former is such that one platinum loopful (two milligrammes) is sufficient to kill a white rat (200 grammes) in 24 hours, $\frac{1}{32}$ th of a loop kills a similar animal in three days, $\frac{1}{128}$ th of a loop in four days, and $\frac{1}{1024}$ th of a loop in six days; while the virulence of the latter is such that $\frac{1}{16}$ th, $\frac{1}{32}$ th, and $\frac{1}{64}$ th of a loop will kill a white rat (200 grammes) in three, five, and seven days respectively. 50 animals on which the curative powder was administered were as follows: 16 guinea-pigs, 24 brown rats, and ten white rats.

In my experiments I have selected the introduction of plague virus in a subcutaneous pouch in the case of brown rats and by a cutaneous method in the case of guinea-pigs and white rats, as the cutaneous method in the case of guinea-pigs and white rats is a certain method of producing the disease, whereas the cutaneous method in brown rats is not so reliable as the subcutaneous pouch.

When working with the Blagdon strain the number of recoveries obtained were 50 per cent. in the case of brown and white rats when plague was given in a subcutaneous pouch to the former and cutaneously to the latter, as two (Nos. 2 and 3 (white rats) and 6 and 8 (brown rats)) out of four animals recovered in both instances. Whereas with Bishopsgate the recoveries obtained were 65 per cent., as eight (Nos. 26, 28, 29, 31, 32, 33, 34, and 36) out of 12 brown rats and four (Nos. 37, 38, 39, and 40) out of six white rats recovered when treated with the remedy. In the case of guinea-pigs the results were more favourable. Four were infected with Blagdon (recovered 3: Nos. 10, 11, and 12) and 12 with Bishopsgate (recovered 8: Nos. 13, 15, 16, 17, 19, 20, 21, and 24) cutaneously. Out of these 16 animals 11 recovered, giving a percentage of a little over 68 recoveries. In these animals one loop (two milligrammes) of agar culture of bacillus pestis of about 48 hours' growth procured directly from the smears of organs of animals dead from acute plague was used in every case and the curative powder administered varied from 100 to 250 milligramme doses. In nearly half of the cases the curative powder was given 24 hours after the infection and in others half an hour after the infection. When plague was given subcutaneously to brown rats the recoveries obtained were 50 per cent., as four (Nos. 43, 44, 46, and 47) out of eight animals inoculated with Blagdon recovered. Out of eight brown rats six had $\frac{1}{32}$ th of a loop (Blagdon) subcutaneously and 150 milligrammes of the powder about half an hour after the infection and the remaining two brown rats had $\frac{1}{16}$ th of a loop (Blagdon) and

¹ Report of a research carried out during the years 1905 and 1906 at the Hygienic Institute, Hamburg.

* Bacillus pestis not found in any organ.

100 milligrammes of the powder about half an hour after the infection. An average-sized rabbit yields about 28 grammes of the powder. The smallest amount of the gland

cure with which a positive result was obtained was 100 milligrammes in the case of brown rats. The Laboratory, Hyderabad, Deccan.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF INFECTION DURING THE PUERPERIUM SIMULATING PSOAS ABSCESS.

By WILLIAM AYRES, B.A., M.D. DUB.

ON April 25th, 1903, I attended a patient in her fifteenth confinement. I had attended three previous confinements. The labour was most uneventful. I arrived just in time to be present at the birth of the child. On the fifth day of the puerperium the patient had a rigor. The temperature was 99° F. and the pulse-rate was 100 per minute. I douched out the uterus and put the patient on a quinine mixture. I examined the uterus and adnexa most carefully but could find no reason for this rigor and as the temperature remained normal I thought I was free from all trace of puerperal infection. On the twelfth day of the puerperium the patient began to complain of pain in her left leg which gradually got worse and the leg began to contract until the knee was at right angles to the body. The pain was relieved by suppositories of morphine. On the fifteenth day of the puerperium a small hard lump of the size of a Tangerine orange began to appear to the left of, and below, the umbilicus. This lump was very hard and immovable and was thought to be an inflammatory swelling in connexion with the broad ligament pressing on the lumbo-sacral plexus; it grew very slowly. The temperature never went beyond 99° and that was reached only once or twice; the pulse-rate was never beyond 100 per minute. On May 18th I had for private reasons to leave my practice and I gave instructions that a colleague should see the case in my absence if the pain became unbearable. My colleague came to the conclusion that the lump was of a cancerous nature owing to its hardness and immovability and also the absence of any very definite temperature and pulse-rate. It was decided, therefore, as there was some doubt as to the exact nature of this lump to give the patient the benefit of an operation. After consultation Dr. F. Edge of Wolverhampton kindly undertook the operation, which was performed at the Nursing Institution, Wolverhampton, on June 9th.

After the preliminary laparotomy a hard lump was discovered behind the sigmoid flexure which was fixed but not involved anteriorly or laterally. As owing to its position removal of the mass if malignant was impossible and incision into it pregnant with danger should not have been struck, as it would have had to drain through the peritoneal cavity, it was decided to await events and the abdominal wound was accordingly stitched up again. The uterus and adnexa were found to be in a perfectly healthy and normal condition. The patient stood the operation well and made a good recovery. The temperature several times reached 101° F. and the pulse-rate varied from 90 to 110. She seemed to be in rather a typhoid condition but at the end of three weeks she improved and went home.

There was no doubt as to sepsis of some kind but it was held to be due to mischief in the sigmoid flexure or infection of the mass from the intestinal canal but the mass was so hard and firm that the possibility of sarcoma was not excluded and the question was raised as to whether an artificial anus might not be required later.

Ten days after the patient's return home the lump suddenly disappeared from above the brim of the true pelvis and presented itself in Scarpa's triangle, where it was seen to be inflammatory, and was accordingly opened. The patient was up and about again in another two months. The lymphatic glands involved were the left common iliac and lower lumbar glands and it is possible that the lesion in such cases is due to injury to the rectal tissues during labour.

A most interesting case of a similar nature has recently been reported by Dr. P. J. Watkins, professor of gynaecology at the North-Western University, Chicago, but there are so many points of difference in the two cases that perhaps a report of my case may be of interest to the profession.

I am indebted to Dr. Edge for the kind use of notes during the time that the patient was under his care.

Brierley Hill, Staffs.

A CASE OF RAYNAUD'S DISEASE.

By JOHN REID, M.D. ABERD.

THE patient in the following case was a child, 14 days old, who presented marked puffiness of the eyes indicating ophthalmia neonatorum; there was also a redness spreading over the head suggestive of erysipelas. The digestive apparatus seemed to be good and the food was breast milk only. The hygienic surroundings were bad. On Jan. 4th the only treatment ordered was the application of flour to the skin. On the 5th a boracic lotion was ordered for the eyes, which soon cleared, and as both thumbs were swollen and hard, suggesting osteomyelitis, mercury was given internally and applied to the thumbs. The toes next gave evidence of osteomyelitis and the left leg was also red in addition to being swollen. The child seemed tolerably well. On the 8th the symptoms of osteomyelitis disappeared and patches of gangrene were to be seen on the toes, fingers, and left forearm, previously red. The gangrene was in each case superficial. The child continued to take calomel in powder. The redness had left the head for some days. Only the big toes and thumbs had the appearance of chilblains, and there was redness round the gangrenous patch over the left forearm. The left ankle was markedly flexed, and the right ankle partially flexed. On the 10th when the child cried the sound emitted had a whining character and there were some laryngeal symptoms without fever. On the 11th the base of the left lung was found to be solid; the gangrene had, if anything, slightly retrogressed. Death occurred quietly about 8 P.M. The mother said that a former child of hers died somewhat similarly. I looked on the case as one of congenital syphilis without snuffles. The red skin preceding the gangrene, is different from Raynaud's cases.

The local application of mercury to the myelitis seemed to have an almost magical effect judging from cases which I have seen treated by constitutional means only.

Walbrook, E.C.

VACCINATION GRANT.—Mr. John Hoole, M.R.C.S., has received the grant for successful vaccination for the Hartington district of the Ashbourne union.

HOSPITAL SATURDAY FUND AT PLYMOUTH.—During 1906 the sum of £627 was raised by the Hospital Saturday Fund for the South Devon and East Cornwall Hospital, Plymouth.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

On the de novo Origin of Bacteria, Bacilli, Vibriones, Micrococci, Torulae, and Moulds in Certain previously Superheated Saline Solutions contained within Hermetically Sealed Tubes.—Idiopathic Cyanosis due to Sulph-Hæmoglobinæmia.

A MEETING of this society was held on Jan. 22nd, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Dr. H. CHARLTON BASTIAN said that early in the year 1906 he began to make experiments on the question of the origin of life with various saline solutions containing ammoniacal salts. After a time he found the best results were to be obtained with one or another of two solutions, one of which contained small quantities of sodium silicate, ammonium phosphate, and dilute phosphoric acid in distilled water, and the other a simple solution of sodium silicate with liquor ferri pernitricis in distilled water. It was found, also, that with the use of these saline solutions exposure of the experimental vessels to diffuse daylight, with even a mean temperature of only from 69° to 65° F., favoured the appearance of micro-organisms quite as much as, or even more than, darkness associated with an incubator temperature of 95° F. The solutions were placed in previously superheated tubes, which, after being hermetically sealed, were heated again in a calcium chloride bath to 239° F. (115° C.), 248°, 257°, or 266° F. (130° C.), for from 10 to 20 minutes. In all these tubes, after the process of heating, a small deposit either of silica alone or of silicate of iron was thrown down. The tubes were subsequently exposed either to diffuse daylight or else in the incubator, and mostly for periods varying from five weeks to four months. When opened the tubes were found to contain, in varying abundance, one or more kinds of micro-organisms, photographs of which were shown. One point of much interest in connection with these experiments was the fact that no carbon was ostensibly contained in the solutions, though its close chemical ally silicon was always present. It had previously been determined that such solutions proved excellent nourishing media for the growth of micro-organisms, and this fact led to trials whether any evidence was to be obtained tending to show that such solutions could also actually engender living units. On examination of the contents of the tubes after their prolonged periods of exposure to light or in the incubator the organisms were always found, after careful search, on or within the substance of the flakes of silica, while the fluid above remained perfectly clear. The fluid would remain in this condition and quite free from micro-organisms, even for months after organisms were known to be swarming in the silica itself. Some of these organisms also were found in flakes of silica taken from tubes from which all air had been expelled by boiling at the time when they were hermetically sealed, so that, except for any carbonaceous impurity that may have existed in the distilled water or in the chemicals employed, no carbon would be contained within these tubes. And even in those tubes which did contain air this was always separated by a deep layer of the fluid itself from the deposit in which the organisms were contained. Many organic compounds had been discovered by chemists in which silicon wholly or in part replaces carbon; and it was contended that there was good *prima facie* evidence from these experiments tending to show that silicon was capable of entering into the composition of protoplasm itself—that is wholly or in part taking the place of carbon. In regard to the major question, concerning the origin of life itself, the facts to be borne in mind were these: If a few hours after the heating of the tubes one or more of them were opened as "control" experiments, and the sediment carefully examined, no organisms of any kind were to be found; but, after suitable periods of exposure, organisms might be found, in more or less abundance, in the sediment taken from other similar tubes. The organisms were, moreover, always motionless; so they must have sprang up and multiplied in the sites where they were found. Then, again, it was important to bear in mind: (1) That, apart from "spores" of bacilli, no micro-organisms could resist an exposure of two or three minutes in boiling

water, this being lethal for bacteria, vibriones, micrococci, torulae, and moulds; and (2) that all ordinary spores of bacilli were killed by a similar exposure for a minute or two to 115° C. (239° F.). It could only be concluded, therefore, that the bacteria, bacilli, vibriones, micrococci, torulae, and moulds which had been taken from hermetically sealed tubes previously heated to 115°, 120°, 125°, and 130° C. for from 10 to 20 minutes must have been engendered *de novo* within these vessels. The organisms that arose *de novo* were presumed by Dr. Bastian to assume well-known forms, for precisely the same reason that the various representatives of the crystalline world, when they originated, invariably fell into their own specific shapes and with surfaces always inclined to one another at angles that never varied for each particular species of crystal. The forms in each set of cases—in organisms and in crystals alike—might be regarded as the necessary resultants of the molecular constitution of their initial units in the particular media and surroundings in which they occurred.

Professor E. H. STARLING said that there was much in the main thesis which Dr. Bastian had propounded with which he was in agreement. In the body the inorganic material taken in was elaborated into organic material—a change which was designated assimilation. Taking the simple sugars as an example it was only the dextro-rotatory which could be so assimilated while the invert sugar could not be so utilised. If they accepted the development of the higher forms of life from the lower forms then the process should not cease at the lowest forms of life and there should be no sharp line between what was regarded as living and what as dead. Even in the body the red blood cells were on the border line and these when killed by formalin gave reactions which were regarded as evidence of living cells. If protoplasm was formed, as Dr. Bastian had suggested, in a primitive form, it would serve as a pabulum for more highly organised bodies, and it was only under such conditions as Dr. Bastian had arranged that such early protoplasm could survive. In relation to Dr. Bastian's experiments the question arose as to whether the organisms which he showed were alive. He did not consider that this was proved and suggested that a plate-culture might demonstrate this, though even under such conditions the organism might be alive and yet not grow.

Dr. E. W. GOODALL said that he was not convinced that the tubes in which the experiments had been performed had been completely sterilised. He asked for proof that the organisms seen in the tubes were living.

Dr. BASTIAN, in reply, said that not only in the preparation of the tubes had they been subjected to a very high temperature, but also after being filled with fluid a temperature of 130° C. had been used for 20 minutes, which all observers agreed was sufficient to destroy all organisms and spores. The evidences of life in the organisms were unmistakable; not only did they increase in the tubes but they could be removed on to a slide and could, under suitable conditions, be seen to multiply there.

Dr. S. WEST and Dr. T. W. CLARKE communicated an account of a case of Idiopathic Cyanosis due to Sulph-Hæmoglobinæmia. The paper, which was illustrated by an epidiascope demonstration, will appear in full in a future issue.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

Laboratory Meeting at the Lister Institute.

A MEETING of this society was held at the Lister Institute on Jan. 12th, Dr. C. J. MARTIN being in the chair.

Dr. J. HENDERSON SMITH read a communication on the Increase of Complement in Serum allowed to Stand in Contact with Clot. He pointed out that while immune serum had its full complement from the beginning, that of normal serum took several hours to develop, and that the increase in contact with clot was much greater than without it. In the discussion following the paper Dr. J. A. CRAW remarked on the increase of opsonin, and Dr. E. W. A. WALKER on the increase in bacteriolytic power when the serum was left in contact with clot—Dr. G. DEAN, examining 18 hours afterwards, could find no difference as regards opsonins.

Dr. J. C. G. LEDINGHAM in a paper dealing with the Quantitative Relationship between the Globulin and the Antitoxin of Diphtheria Anti-serum, was inclined to conclude from a small number of cases examined that horses

showing a large amount of globulin might be discarded for purposes of immunisation as likely to prove unsatisfactory. He also showed how during the process of immunisation the globulin rises with the potency.

Dr. CRAW and Dr. DEAN, in a conjoint paper on the Standardisation of Diphtheria Toxin and the Normal Variations in the Weight of the Guinea-pig, criticised the results of Arrhenius and Madsen with regard to the relations between lethal dose, lethal time, and weight of animal.

Dr. DEAN, in a paper on Further Experiments on the Nature of the Substance in Serum which Influences Phagocytosis, concluded that the number of organisms taken up by phagocytes in opsonic technique was directly proportionate to the concentration of the emulsion and that the complement corresponded with the opsonin of normal serum.

Professor R. MUIR and Dr. W. B. M. MARTIN continuing the researches the results of which were submitted to the society at Manchester last summer, read a short paper on the Combining Properties of Opsonin and Immune Serum. They found that substances which took up complement of normal serum also fixed opsonins. Heating brought out differences between opsonins of normal serum and that of immune serum, for whilst the former were destroyed at 55° C., the latter had something remaining constant. No substance combined with immune opsonin except the organism producing it. In addition to heat they used other complement absorbers, such as red blood corpuscles and immune body. Contrary to Bulloch's conclusions, they found that there was a fall in opsonic power when normal serum was treated with various organisms, whereas treatment had no effect on immune opsonin. They concluded that immune opsonins were real anti-substances. The question of their constitution—whether they were of the type of immune body or agglutinin—they left open.

Professor D. J. HAMILTON raised the question of the practicability of Multiple Immunisation. He spoke briefly regarding the results recently obtained in the West Highlands and South of Scotland and also in Ireland in endeavouring to immunise sheep against "louping ill," chorea paralytica, and diseases "A" and "B," the organisms of which he described at the Manchester meeting. The mortality, which had ranged from 15 to 50 per cent. (among non-immunised sheep), had fallen to 1.5 per cent. in animals immunised by the mouth. Fuller details were promised in the forthcoming report of the Agricultural Board.—Colonel LEISHMAN briefly stated that in researches on typhoid fever mouth immunisation seemed to give definite evidence of some immunising substance.

Colonel LEISHMAN, R.A.M.C., read a paper on Monkey Malaria, founded chiefly upon smear preparations from three monkeys brought back from Uganda by Bruce and on other films prepared by Greig in Uganda. The persistence of parasites in the blood was noticed, sometimes few, sometimes many; they were never absent, but no periodicity was observed. Free gametes, macrogametes, and intracorporeal forms were met with. Rosette formation was never observed, and while Colonel Leishman did not suggest that such did not occur, he pointed out that the absence of such formation was remarkable. He thought that the fresh supply in the blood depended on an alternative mode of propagation—namely, that it was due to extrusions of chromatin from the macrogametes and that these extrusions became fresh malarial parasites.—Professor E. A. MINCHIN, remarking on Colonel Leishman's paper, said that such protozoa had three forms: (1) The male, practically all nucleus, which soon died off; (2) the indifferent form which was hardier and lasted longer; and (3) the female macrogametocytes, which by parthenogenesis (as suggested by Schaudinn) could give rise to the indifferent form.

Dr. S. MONCKTON COPEMAN and Dr. W. HARE made a communication on the Presence of Hydrochloric Acid in the Stomachs of Mice Inoculated with Cancer.

Dr. M. S. PEMBREY spoke of the Effects of Exercise. He observed that there was an optimum temperature for exercise, that muscular exercise raised the temperature, and that it must be taken into account that the normal temperature might sometimes reach 100.5° F. He found that the blood pressure fell after exercise owing to dilatation of the peripheral vessels, and that though the depth of respiration was changed the rate practically did not vary.

Dr. J. B. LEATHES made a communication on Metabolism in Fever, in which he said that in fever induced by typhoid vaccine the total nitrogen, kreatinine, and especially uric acid were increased.

Dr. F. A. BAINBRIDGE and Dr. A. P. BEDDARD submitted the results of Experiments on Cats in which portions of the kidneys were removed at two operations. They failed to find any evidence that the kidneys influenced nitrogenous metabolism.

Mr. H. W. ARMIT read the results of his chemical researches on the Toxic Actions of Iron and Nickel.

Dr. J. S. HALDANE, Lieutenant DAMANT, R.N., and Dr. A. E. BOYCOTT submitted some Observations on Caisson Disease. While pressure *per se* had no effect, the ill-effects experienced were due to decompression setting free bubbles of air. As continuous decompression necessitated a considerable time, men working in caissons rebelled against it, and an endeavour was made to shorten the decompression period without adding to the risks. Instead of continuous decompression they found that decompression by "jumps"—great at first and then by slower and smaller steps afterwards—gave much better and safer results.

Professor J. LORRAIN SMITH contributed a supplementary paper to that submitted at Manchester on the Staining of Fat with Aniline Dyes. The method of staining fat by basic aniline dyes depended on the hydrolysis of neutral fat yielding fatty acid to unite with the colour base on exposure to air. The staining especially with methyl violet seemed to be permanent. He now obtained permanent preparations by mounting the sections in gum acacia. By using a saturated watery solution of Nile blue sulphate A he was able to differentiate fatty acid from neutral fat, the former staining red while the latter stained blue. The transitions between fatty acid globules and neutral fat globules could be brought out in certain conditions. A demonstration of the staining results was given by beautiful three-colour lantern slides prepared by Dr. W. J. S. Bythell.

Dr. J. MILLER described the appearances found post mortem in an early case (seven days) of Acute Poliomyelitis. There was a soft swelling of the cord in the cervical region which gave on culture the staphylococcus pyogenes citreus. The various theories of causation were discussed but Dr. Miller favoured the view that the condition was inflammatory.

Dr. W. E. CARNEGIE DICKSON gave a lucid description of a unique case of Polyarteritis Acuta Nodosa. This he differentiated from periarteritis nodosa. The disease seemed first to start in the vessel wall (the muscle) and the thrombosis of the small aneurysms occurred secondarily. The paper was well illustrated and was supplemented by a microscopic demonstration. Though giant cells were found in the lesions no tubercle bacilli or spirochaete could be observed by staining, yet the idea of inflammatory causation could not be put aside.—Professor MUIR contrasted the microscopic appearances with those of a case of polyarteritis nodosa described by Bruce and himself.

Dr. S. G. SCOTT and Dr. W. H. M. TELLING exhibited the specimen and read short notes on a case of Marginal Hemorrhagic Necrosis of the Liver. The margin of the liver, except where in contact with the diaphragm, was of a much darker colour than the rest of the parenchyma and in this margin the liver cells had disappeared. The necropsy, which was unfortunately incomplete, was performed 18 hours after death and revealed no cause for this appearance.

Dr. F. G. BUSHNELL read notes on a case of Generalised Sarcoma. He was inclined to think that leukaemia might be regarded as a malignant reproduction of white blood cells.

Dr. O. POWELL WHITE and Dr. W. MAIR demonstrated an interesting case of Primary Malignant Tumour of the Liver. There were no metastases and the adrenals were normal. From its histological characters they concluded that it had arisen from a suprarenal rest in the liver. Though these rests are usually found in the right lobe this tumour was confined to the left.

Dr. F. CRAVEN MOORE gave a demonstration on a case of Endothelioma of the Stomach. He fully described a case and considered it to have arisen from the lymphatic endothelium of the submucosa.

The following demonstrations of specimens were given in various rooms by: Dr. MILLER on a case of Acute Poliomyelitis.—Dr. CARNEGIE DICKSON on Polyarteritis Acuta myelitis.—Dr. TELLING and Dr. SCOTT on Marginal Necrosis Nodosa.—Dr. BUSHNELL on Generalised Sarcoma.—Dr. of the Liver.—Dr. BUSHNELL on Adrenal Tumour of Liver. POWELL WHITE and Dr. MAIR on Structure of Trypanosomes.—Mr. H. G. PLIMMER on the Structure of Well-defined High along with a Simple Method of Obtaining Well-defined High Magnifications.—Professor MINCHIN on Division of Trypanosomes Grayi.—Dr. O. J. MARTIN on a New Water-driven Centrifuge.—Dr. O. W. ROWNTREE on an Improved Method

of Mounting Museum Specimens.—Dr. A. G. GIBSON on Malignant Tumour of the Liver.—Miss MABEL FITZGERALD on Calicines of Trichophyta from Cases of Tinea.—Dr. I. WALKER HALL on Tumour of Recto-vaginal Interspace.—Dr. J. D. THOMSON on a Parasite in the Red Blood Corpuscles of the Moie.—Professor A. S. F. GRUNBAUM on the Monkey Brain in Syphilis.

The next meeting will be held in June at Edinburgh.

EPIDEMIOLOGICAL SOCIETY.

Real and Apparent Differences in the Incidence of Cancer.

A MEETING of this society was held on Jan. 18th, Dr. JOHN F. W. TATHAM, the President, being in the chair.

Dr. E. F. BASHFORD (general superintendent of the Imperial Cancer Research Fund) read a paper on Real and Apparent Differences in the Incidence of Cancer. Having drawn attention to the great difficulty of recognising cancer clinically, and reviewed the differences in the recorded incidence of cancer in Europe, Japan, India, and other lands, and having discussed the reasons for the difference between England and Ireland, Dr. Bashford concluded that the magnitude of the differences was more apparent than real. The real differences that probably existed were obscured. It was pointed out that, contrary to general opinion, cancer was approximately as common a cause of death in Japan as in England and any weight attaching to the argument that the frequency of cancer was the result of European civilisation was thereby removed. One phenomenon of universal occurrence in civilised and uncivilised man, in domesticated and in wild animals, had more importance than all variations. The increasing frequency of cancer with advancing age was a law generally applicable to the vertebrates, whether the absolute length of life was short or long. The peculiar incidence of cancer in childhood was a special manifestation of the same law with reference to fetal structures. The incidence of cancer in the different organs of the body was analysed with the object of eliciting whether there was a progressive increase to the utmost limits of life or a rise to a maximum followed by a fall as in the case of fatal structures. The investigation of cancer could be profitably pursued statistically and experimentally either (1) from the standpoint that its incidence obeyed the definite biological laws which governed the growth and the length of life of organisms as a whole and of their individual organs because it arose *de novo* in each sporadic case; or (2) from the standpoint that the several cases occurring sporadically are causally connected by an infecting virus which produces its effects in conformity with the same biological law. The balance of evidence was stated to be in favour of the first view. Dr. Bashford concluded by expressing indebtedness for the assistance given by the Registrar General's office. In no other country had the national statistical office vouchsafed so much collaboration. In view of the fact that the only trustworthy estimation of the frequency of cancer was the national death-rate this collaboration was of unique value.

The PRESIDENT said that as regards the cure of cancer the consequences described by Dr. Bashford of the inoculation of mice with a quantity of tissue no larger than the point of a pin showed how rational was the modern surgical treatment of the disease. The early surgical removal of the small piece of tissue at the site of inoculation prevented the diffusion of the disease and the formation of secondary deposits in remote parts of the body. That evidence demonstrated the necessity for the prompt removal of the smallest growths as was now constantly advocated by surgeons and too often as constantly neglected by patients. There was little hope that within a reasonable time primary growths would be amenable to anything short of absolute removal. From the fact, however, that animals could be rendered unsuitable for the growth in their bodies of malignant processes, it was hoped that eventually the power of the resistance of the organism might be so far enhanced that the cells disseminated from the site of inoculation should be unable to grow. The manner in which carcinoma could be transmitted from individual to individual had now been so fully established experimentally as to be no longer in doubt. The experimental transference of the

animals. That was an absolute contradiction to what might have been, and as a matter of fact was, expected. That difference between young and old animals was especially important in determining the conception of the etiology of cancer. The greater frequency of cancer in later life was not therefore due to increasing suitability for the growth of cancer. Mice could be protected against successful inoculation by preceding inoculation of cancerous tissue from another mouse, but not from an animal of another species. But the fact to which Dr. Bashford attached supreme importance, and which the President said surprised him greatly, was that an equally high degree of protection could be conferred by the inoculation not of cancerous but of perfectly normal tissue, healthy blood in fact, from one healthy animal into the body of another of the same species. That fact was pregnant with future possibilities.

Dr. J. F. PAYNE said it was startling to find that young animals were more susceptible than old animals. He did not think that the statistical returns from Scotland were so good as those from England and Wales. According to statistics the first years of life showed a high rate of mortality and he thought that was due to sarcoma being so common at that age. Dr. Payne called it infantile sarcoma. *These sarcomata in the young were seldom pure and were probably of congenital origin.* In regard to the statistics for deaths from primary cancer of the liver he considered that many of those should be ascribed to secondary cases of cancer occurring in the liver arising from primary cancer elsewhere.

Dr. A. NEWSHOLME said that by the statistical method of investigation it was shown that civilisation was not an essential factor in the causation of cancer. The occurrence of cancer in fish and in the lower animals was considered to be in the same proportion as in man and it was noticed that meat-eating was not necessarily an essential factor in the causation of cancer.

Dr. F. W. ANDREWES emphasised the fact that in the early years of life the mortality from cancer was due in the great majority of cases to sarcomatous tumour, especially sarcoma of the kidney.

Sir SHIRLEY F. MURPHY said that it had been shown from the study of the figures in well-to-do and poor districts that the incidence of cancer in the rich and the poor was very much the same.

Dr. DAWSON WILLIAMS said that it was important to bear in mind the facts referred to by Dr. Payne in regard to what he had called infantile sarcoma. Attention had been drawn to the connexion between cancer and senescence, but the question arose also in regard to obsolescence. All through fetal life the process of obsolescence was going on and continued in connexion with certain organs after birth.

Dr. BASHFORD, in reply, paid a high tribute of praise to the work of his colleagues on the Imperial Cancer Research Fund, and announced that Dr. J. A. Murray had prepared a microscopical demonstration of sporadic and experimental cancer in mice for the inspection of the members attending the meeting.

LIVERPOOL MEDICAL INSTITUTION.

Acute Haemorrhagic Pancreatitis (Three Cases with Operations).—The Etiology of Inguinal and Femoral Hernia.—Ventrification of the Uterus.

A MEETING of this society was held on Jan. 17th, Mr. FRANK T. PAUL, the President, being in the chair.

Mr. W. THRELWALL THOMAS read a short note on three cases of Acute Haemorrhagic Pancreatitis operated upon with two recoveries. The first patient, a female, aged 56 years, was in *extremis* 35 hours after the onset of acute abdominal pain with vomiting, quickly becoming fatal. On incision, under eucaine, blood-stained effusion escaped from the abdomen and the omentum was in a condition of fat necrosis. The patient succumbed a few hours later. Post mortem, haemorrhagic pancreatitis was found. The second case occurred in a woman, aged 21 years, in whom the symptoms resembled perforation of a gastric ulcer, but with rise of temperature. The condition became rapidly worse and on operation fat necrosis of the omentum was found with copious effusion of blood-stained material into the peritoneal cavity. The lesser peritoneal sac was drained by a loin drain and an anterior tube as well as a tube into the pelvis. 35 gall-stones were removed from the gall-bladder and the latter was drained.

The pancreas was much enlarged but without hæmorrhages. The patient made an uneventful recovery. The third case which occurred was that of a man, aged 40 years. The onset was acute and a diagnosis of intestinal obstruction was made. There was a rise of temperature with slight vomiting and the abdomen became rigid and tender. On incision, 36 hours after onset, fatty necrosis in the extra-peritoneal tissue, omentum and mesentery was found. The gall-bladder, which was full of inspissated bile, and the peritoneal sac were drained as in the previous case. The pancreas, which was very much enlarged and hæmorrhagic, was incised. The patient made a good recovery, but with a pancreatic fistula which remained open for six weeks. Mr. Thomas then discussed the etiology and treatment of the disease.—The cases were discussed by Mr. R. W. MURRAY, Mr. G. S. STANSFIELD, and Dr. A. G. GULLAN.

Mr. R. W. MURRAY read a note on the Etiology of Inguinal and Femoral Hernia, based on a series of post-mortem observations made upon 200 persons in whom during life there was no evidence or history of hernia. Amongst the 200 bodies examined, 68 peritoneal diverticula were found, 52 in the femoral and 13 in the inguinal region. Arguments were advanced in favour of the saccular theory of hernia, and Mr. Murray contended that all the evidence they at present possessed was in favour of the belief that a preformed sac is the essential cause of inguinal and femoral hernia at all periods of life.—Dr. T. R. BRADSHAW said that granting that an oblique hernia came down the inguinal canal, a direct inguinal hernia could not have such an origin. One important clinical fact made it difficult for him to accept the view that the tunica vaginalis was frequently found communicating with the peritoneum in persons who were not the subjects of herniæ—viz., the extreme rarity with which the fluid of ascites was found in the tunica vaginalis. He had only once seen such a case, more than 20 years ago, and in that case the fluid could easily be made to pass from the tunica vaginalis into the abdomen, or *vice versa*, by changing the patient's position.—Mr. Murray's paper was also discussed by the PRESIDENT, Mr. F. O. LARKIN, and Mr. K. W. MONSARRAT.

Dr. HENRY BRIGGS read a paper on Ventrofixation in the Treatment of Backward Displacements of the Uterus. The exemption of the "blooming, happy, and fertile" woman from any treatment whatever was claimed. During the child-bearing period of life he advocated the limitation of pessary treatment to recent cases of retroversion or retroflexion after manual reduction of the displacement, and for chronic backward displacement of the uterus with complications he urged the superior position of ventrofixation and founded his opinion upon the clinical records and the after-histories of 203 cases treated by him during the past seven years. In all the 203 cases the patients recovered. The after-histories of all the patients, with the exception of the nine unobtainable and a few too recent to be of value, were added. An analysis of the cases in the five groups, A, B, C, D, and E, illustrated the extent and character of the complications of backward displacements of the uterus. Table A: 98 cases of backward displacement before operation were characterised by (a) uterine descent in a minor degree in all of them; (b) ovarian prolapse, on one side 13, on both sides 26; (c) inflammatory cystic changes in the ovary, 3; and (d) apoplexy and thickened capsule of the ovary, 6; and were treated by ventrofixation of the mobile uterus; the relief afforded was complete in 64, partial in 22, and disappointing in 7 patients; one single woman, aged 23 years, who had suffered from distressing dysmenorrhœa since puberty, was totally unrelieved by ventrofixation performed after a previous dilatation and section of the cervix had also failed to relieve her. Table B: 41 cases, ventrofixation with perineorrhaphy, colporrhaphy, trachelorrhaphy, dilatation, and curettage, i.e., a combination of two or more operations of which one was ventrofixation, showed relief complete in 24 partial in 9, and disappointing in 5 patients. Table C: 24 cases ventrofixation with separation of adhesions and in seven instances salpingostomy (conservative operations); recorded instances of relief complete in 13, partial in 8, and disappointing in 1 patient. Table D: 31 cases, ventrofixation with removal of one tube and ovary; relief complete in 20 and partial in 7 patients. Table E: 9 cases, ventrofixation with removal of both appendages; relief complete in 7 and partial in 1 patient. Complete relief after ventrofixation persisted throughout all the groups in almost the same proportion of cases. That is substantial evidence of a pathological

element in the aggregate of the backward displacements in Table A. The lowest proportion of complete relief followed the total conservative treatment of pelvic peritonitis, due probably to obscure, active or latent, germ infection: (Table C) in 24 cases pregnancy is unknown after operation, except in one instance. Dr. Briggs then explained his preference for purely parietal peritoneal fixation at the summit of the empty bladder at the lower end of a two-inch abdominal incision ending one inch above the pubic symphysis. The Trendelenburg position enabled the operator to suture closely this central lowest portion of the parietal peritoneum to the middle two-fourths of the lower half of the anterior surface of the uterine body, in which the sutures were planted through muscle one-eighth of an inch deep. No. 2 Chinese silk was used for the fixation. Dr. Briggs said he had discontinued since 1903 catgut for this purpose only. The abdominal wound was closed in three layers by catgut sutures, the finest catgut always for the skin. The advantages of peritoneal fixation were the slight uterine mobility it insured; in the latter advantage Dr. Briggs agreed with Küstner and the further advantages of less inconvenience to the bladder and the ease and safety of subsequent labour and pregnancy were realised. Dr. H. Russell Andrews, in his digest in 1905 of all ventrofixations then published, had found the least interference with labour after peritoneal fixation. Amongst Dr. Briggs's cases in Table A alone 22 women had borne 32 children; normal labour was the rule and easy forceps delivery the exception. In one patient who had had five children (twins once) since the operation uterine inertia during the third stage had been observed and was not noted before operation by Dr. J. Masson of St. Helens. Dr. Briggs said that cervical and intra-uterine, vaginal and perineal complications were advisedly treated if necessary before the abdomen was opened, that abdominal section dealt with the peritonitic bands and their causes, and that ventrofixation completed a safe and satisfactory operation for retroversion or retroflexion during the child-bearing period of life.—Dr. T. B. GRIMSDALE thought that the title of the paper exaggerated the importance of the backward displacement of the uterus and seemed to imply that all the symptoms were due to the backward position of the uterus, whereas all of the cases referred to showed other pathological conditions which were in all probability responsible for the symptoms present, the backward displacement being merely an incident in the case. As to the operation of ventrofixation itself, it was safe and effective if properly performed, though the holding capacity of the bladder seemed to be diminished slightly by it.—Dr. W. BLAIR BELL thought that the pathology of retroversion and retroflexion was not always the same. He had applied his own views to Dr. Briggs's statistics and found there much to support those views; for instance, he found that of the total failures 75 per cent. were in single women, and further, that of the cases, whether single or married, complaining of menorrhagia 85 per cent. were completely cured, while only 62 per cent. of the total number of cases were cured. These facts he considered important, as were some others to be deduced from the figures. He (Dr. Bell) thought all forms of ventrofixation unsurgical and dangerous, particularly the operation of peritoneal attachment described. He much preferred Gillian's operation, which he had now performed in a modified form for over a year, or one of his own, first performed in March last, in which a loop of round ligament on each side was brought through the broad ligament and fixed behind the uterus, an operation which had been recently independently described.—Dr. ARTHUR J. WALLACE remarked that ventrofixation was not a scientific procedure, but in default of a better it was satisfactory in that it relieved the patient. The principal drawback was that between the utero parietal attachment, the abdominal parietes, and the bladder there existed a potential opening or tunnel through which a loop of intestine might pass and become strangulated. A perfect procedure should bring about the formation of a complete peritoneal septum between the uterus, the bladder, and the abdominal wall. When the direct utero-parietal attachment stretched a little, as it appeared to do usually, there would result a kind of anterior mesometrium dividing the utero-vesical pouch into two halves, without any opening through which intestine might pass.—Dr. J. E. GEMMELL, Dr. E. T. DAVIES, and Dr. BENNETT also took part in the discussion on the paper.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Loss of the Stereognostic Sense.—Some Improvements in Cutaneous Therapeutics.—Electrical Conductivity of the Blood and Urine in Health and Disease and as a Test of the Functional Efficiency of the Kidney.—Some Cases treated by Bier's Method.—Notification of Infectious Diseases

A MEETING of this society was held on Jan. 16th, Dr. J. O. AFFLECK, the President, being in the chair.

Dr. BYRON BRAMWELL exhibited a case showing Loss of the Stereognostic Sense. The patient, a man, aged 37 years, on Jan. 30th, 1905, was struck on the left side of the head with a heavy stone. He remained unconscious for four days. There was a large hematoma over the left side of the head, but no fracture of the vault could be made out. It was thought, however, that the base of the skull had been fractured because of hemorrhage from the left ear. Weakness of the right arm persisted for some time. Later the speech became stammering in character. He remained in hospital for some time. There were marked disturbance of sensation in the right hand, imperfect localisation, also disturbance of sensation to pain, heat, cold, &c., and total inability to determine what was in his hand when his eyes were closed (stereognostic sense). Under suggestive treatment speech improved. On Nov. 24th, 1906, he returned with stammering speech and loss of sensation over the whole of the right side; there was no wasting of the muscles. On shaving his head a distinct depression was seen over the left parietal bone behind the motor areas and closely corresponding to the area for the stereognostic should sense. The question remained if a section of bone be removed to relieve any compression which might exist.

Dr. W. ALLAN JAMIESON, under the head of "Some Improvements in Cutaneous Therapeutics," showed: 1. Epicolloid and its Combinations. He said that in 1893 Dr. Leslie Phillips directed attention to a proprietary substance called "Kristaline," a celluloid varnish which was used to give a transparent and indestructible protection to metal ornaments as a colourless film which prevented oxidation. This he stated was a solution of pyroxilin in wood naphtha or methyl alcohol. It had a peculiar odour, recalling that of amylnitrite or pineapple drops. This he recommended as a substitute for collodion but it never obtained the notice which it deserved. Much more recently a similar preparation, having the attractive name of "New Skin," had been introduced and had a considerable reputation and sale. At Dr. Jamieson's request Messrs. Duncan, Flockhart, and Co. had prepared a solution of pyroxilin in acetic ether, to which they have given the provisional name of "Epicolloid." This had been tinted a pale pink in order that it might more nearly approximate the colour of the skin. It had the advantage over collodion, even the flexible sort, that, drying more slowly, it formed a closely adherent, smoother, finer, more pliant, and impervious coating, firmer than "New Skin" and less pungent than "Kristaline." It was useful when any abraded surface, after purification, called for sealing up, and particularly so in the treatment of the troublesome cracks in the lips, so apt to occur in the central commissure or at the angles. If a thicker layer was required and opacity was not objected to, this combination with oxide of zinc would be found handy and was adapted for the early stage of herpes zoster. Salicylic acid could be incorporated with it, and in this form it was appropriate for warts and corns. 2. Ichthyol Court Plaster. Dr. Jamieson said that sometimes they wanted a dressing of a more solid kind, and for such cases a thin plaster was the most efficient. British court plasters were all, in his experience, spread on too thick a silk, hence they could not be got to lie close enough to the surface; they tended to curl up, and in all cases soon separated or washed off. He had found the ichthyol court plaster quite an ideal one, especially for small spots of rodent ulcer after scraping and cauterisation with fused chromic acid. A piece of this slightly moistened, adjusted, and pressed down formed a covering scarcely noticeable. It would adhere for days, and it was essential for the success of this method that the part should be kept dry and undisturbed. Applied to the red portion of the lip, it was indistinguishable from the natural surface. There were many other uses for

which these articles could be employed, but to enumerate them would lead into too long a dissertation.

Dr. DAWSON F. T. TURNER read a paper on the Electrical Conductivity of the Blood and Urine in Health and Disease and as a Test of the Functional Efficiency of the Kidney. He said: It would appear from the observations, now some 1000 in number, that the observed resistance of a normal urine amounts to about 250 ohms in this apparatus (specific resistance 42.5 ohms), and from experiments on artificial urines it was found that the resistance depends only upon the ionic concentration—i.e., upon the salts, acids, and bases, and of these NaCl is by far the most important; the resistance for practical clinical purposes can be regarded as being unaffected by the presence of albumin, sugar, blood, and other non-electrolytes. In health the resistance is low, and the lower it is, other things being equal, the healthier the condition. In certain acute and chronic diseases a very high resistance is found constantly present. Acute croupous pneumonia is an example of the former and diabetes mellitus of the latter, but the resistance is also high in kidney disease and in pernicious anemia. The resistance of the urine may rise in a characteristic way during an attack of sick headache. Within the last ten years I have made many attempts to measure the electrical resistance of the blood; various methods (dilution with distilled water, measurement of the resistance of a column of blood in a capillary tube, &c.) have been employed and subsequently rejected. The principal difficulty depends upon the fact that only very small quantities of blood can generally be obtained at one time. The best and most recent results were obtained by placing five cubic millimetres of freshly drawn blood between two cup-shaped electrodes, three millimetres in diameter, coated with spongy platinum, and fixed at two millimetres apart. The length of the cylinder of blood between the electrodes is of less importance than its diameter, because the cross-sectional area varies with the square of its diameter and the resistance of a conductor varies directly as its length and inversely as its cross-sectional area. By employing electrodes of fixed diameter and at the same distance apart and the same quantity of blood for each observation, and by making the measurement at once, before such changes as coagulation or evaporation could occur, fairly consistent results were obtained. Still, as in all blood-measuring operations, practice and the personal equation come in. The average observed resistance of normal blood measured in this way is 900 ohms, but it may fall to 700 or rise exceptionally to 1600 (specific resistance about 150 ohms). The resistance depends again upon the salt concentration of the blood and upon the relative volume of the corpuscles to the serum.¹ These have opposite effects. Thus, the greater the salt concentration the lower the resistance, but the greater the number of red cells present the higher the resistance. A blood of high resistance indicates that the proportion of salts in the blood is small or that the proportion of corpuscles present is large. Hence, a high resistance of the blood but a low resistance of the urine is indicative of health. Changes are to be observed in disease and those changes are in the direction of a diminished resistance; thus in kidney disease, in chlorosis, anemia, and in pernicious anemia, the resistance will be found to be low and sometimes, as in pernicious anemia, very low, even to less than half that of normal blood. In these conditions the blood we must conclude contains fewer blood corpuscles or more salts or both. We can throw light on this question by counting the blood corpuscles and by examining the resistance of the urine; the latter will, as already explained, be found to be high. Dr. F. O. Hopkins (Guy's Hospital Report for 1891) reports that the salts were deficient in the urine in five cases of pernicious anemia which he examined. Proceeding in this way I was led to compare systematically the resistance of the blood and the resistance of the urine and to originate a ratio which after consultation with Dr. G. A. Gibson he has termed the "hæmrenal salt index" or the ratio of the electrical resistance of the blood to the electrical resistance of the urine. In health this would be equal to three, four, or five whole numbers—viz., $\frac{900}{225} = 4$.

The higher this number is the healthier, other things being equal, is the condition of the patient. If the index increases it indicates that the blood contains fewer salts or is richer

¹ Dr. Turner expressed his indebtedness to Professor G. N. Stewart for drawing his attention to the part which the blood corpuscles play in altering the blood resistance, and to Mr. T. M. Wilson's conductivity measurements and cryoscopic observations.

in corpuscles, and that the urine contains more salts and that the functional activity of the kidney is increasing; if the renal index diminishes then the kidney is becoming sluggish and less efficient. Dr. Turner narrated several cases to illustrate the fact that where the index figure was low the kidney was inefficient and frequently diseased as proved by subsequent operation. It would probably be found in the future that the method would be of even more value in surgical affections of the kidney in order to ascertain the renal capacity before deciding whether to undertake an operation. He had not had sufficient opportunities of comparing the method with cryoscopy to permit him to draw any conclusions as to their relative value; in the case of Mr. Q. A. Cathcart the indications of both methods were in agreement, but he would point out at any rate that this was a much more rapid method of clinical diagnosis than cryoscopy and that it was another example of the application of precise scientific measurement to clinical medicine and surgery.—The PRESIDENT, Dr. HARRY RAINY, and Mr. J. M. COTTERILL took part in the discussion which followed.

Dr. T. M. BURN-MURDOCH read a note on Some Cases treated by Bier's Method. The practical nature of the following short notes on some cases treated by Bier's method, he said, was his excuse for bringing them before the society, as they afforded additional proof of the value of Bier's method to the general practitioner. The first case was that of a lad suffering from an injury to his shin, the result of a knock against a form received on Jan. 18th, 1906. He was first seen on the 20th when he complained of acute throbbing pain over the centre of the tibia with swelling of the part. A superficial grazed wound was present. His temperature was normal. By evening his temperature had risen to 102.2°F ., his pulse was 120, and pain was acute. The symptoms so resembled those indicative of an acute osteitis or quite probably an acute osteomyelitis that it was thought an operation would be necessary to check the disease. Mr. Cathcart saw him with Dr. Burn-Murdoch late at night and suggested applying Bier's bandage and postponing operation. This was done and the temperature steadily fell, becoming normal on the 23rd and remaining so with the exception of one slight rise. The pain subsided immediately after the application of the bandage and the boy slept fairly well. Slight subperiosteal suppuration occurred but no operative treatment was necessary. The boy made a rapid recovery, re-entering school in about a month's time. The second case was that of a lad who was seen first on May 30th at 4 o'clock in the afternoon on account of pain and tenderness in the lower end of the tibia. The temperature was then 100.2° . By 9 P.M. the temperature had risen to 103.5° . The pulse was 120 and the pain was acute and throbbing. The pain was localised to about three inches of the lower end of the tibia. It was thought the case might require surgical interference so Mr. Cathcart was asked to see him. He concurred in the diagnosis of acute osteomyelitis, but thought Bier's bandage might safely be tried. This was done with marked relief of all symptoms. The pulse on the 31st—the day after the application of the bandage—ranged from 74 to 98. The temperature did not exceed 102° . On June 1st the pulse did not exceed 90 nor the temperature, 101° . By the 8th the temperature and pulse were normal, both having come down gradually. On June 21st slight periosteal thickening remained at the lower end of the tibia with very slight pain on pressure. The boy re-entered school about five weeks from the commencement of his illness. The third case was one of obstinate ulcers of the leg. The patient, a female, was first seen in the summer of 1905 for incipient ulcers of the leg. These ulcers were preceded by nodular swellings which gradually softened, became blue-red in colour, and then broke down, leaving indolent tuberculous looking ulcers with callous edges. Dr. Burn-Murdoch recognised them as similar to a series of very intractable sores he had twice had to treat in a man with a marked tuberculous history, as evidenced by cicatrices about the neck and axillae. They occurred both on the patient's back and legs. The results of innumerable kinds of treatment, including some suggested by a consultant, proved so unsatisfactory that it was decided at once to send the patient in question to Chalmers Hospital, where she went on August 8th, 1905. Many kinds of dressings were applied without benefit. On August 22nd the ulcer was excised, or probably two of them. No tubercle bacilli were found. The healing process was not satisfactory

and soon broke down, necessitating scraping on Sept. 6th. On Nov. 13th the patient was discharged with the ulcer not fully healed and an unhealthy tuberculous-looking scab was also present. The wounds almost immediately opened up again. She spent a short time in Edinburgh but was sent to Callander for about three months during December, January, and February. The late Dr. MacLaren, to whose care Dr. Burn-Murdoch sent her, urged the importance of rest and open-air treatment, and subsequently informed the latter that she had had an attack of pleurisy from which she recovered well. She returned to Edinburgh early in March with an ulcer of about the size of half a crown on the leg. She sought hospital advice and was advised to have another operation but would not consent. Dr. Burn-Murdoch saw her on March 7th and employed ordinary cleansing dressings to the wound, making her rest in bed. After a few days Bier's bandage was applied with the most beneficial result. The ulcer, which he had despaired of healing, closed over in, to him, an astonishing manner in ten days. She was able to go to Orkney in the first week of April. Dr. Burn-Murdoch heard from her only the other day that the ulcers remained soundly healed. He had had several cases of acute osteomyelitis with symptoms similar to those described in Cases 1 and 2 operated on with the happiest results, but the period of time that the patients took to convalesce and which elapsed before they could return to work greatly exceeded that in the cases described. The history of the ulcer case, of course, spoke for itself.

Dr. ALEXANDER JAMES read a note on the Notification of Infectious Diseases. He said that he was one of the practitioners who believed that in the causation of phthisis infection was a factor of such relatively small importance that the compulsory notification of this disease as an infectious disease was, in the majority of cases, quite unnecessary. Further, he was one of those who held that its compulsory notification in all cases would be mischievous as diverting attention from the most important factors in its causation and would be harsh and cruel to the individual, as it would handicap still more heavily those who were struggling against their infirmity to earn their living. The gist of the argument of those who were in favour of the compulsory notification of phthisis was as follows: Granting that the tubercle germ was present in a large number of healthy individuals (from 40 to 90 per cent.), and granting that a lowering of the general nutrition gave this germ its power to produce its ravages, yet if notification were insisted on this germ would in time be stamped out and thus, however low the general resistance might be, the germ would not be there to make matters worse. In Edinburgh the compulsory notification of infectious diseases had been in force for over 20 years and thus they could compare the mortality from such diseases for periods of years before and after notification. They might therefore form an idea of what notification had done in the way of prevention. Taking phthisis mortality first the chart exhibited showed that it had undergone a very distinct and marked diminution and this was due to the gradual and progressive improvement in the condition of life of the people in the three towns (Edinburgh, Dundee, and Aberdeen). The improvement in the mortality from typhoid fever was gradual but not so marked as in the case of phthisis. The same was true with the group as in the case of diphtheria and croup, but again it was difficult to detect any distinct improvement during the notification period. With scarlet fever improvement was also shown but in this case the indications were that notification had produced improvement. With measles it was obvious that after notification and efforts to stamp out the disease the mortality had actually increased. Dr. James said that notification and efforts to stamp out the germ had at least not been so successful as was anticipated and that the improvement had not been at least more marked than it had been in the case of the phthisis mortality without notification at all. Such being the results of notification what was to be expected of a similar notification and efforts to stamp out the germ in the case of pulmonary phthisis? 1. Differences of opinion existed as regards the mode of entrance of the tubercle germ into the human body; some, like von Behring, believed that it entered mainly in infancy with the milk from tuberculous cows; others, like Koch, believed that the disease was caused mainly by inhalation of particles from dry tuberculous sputum suspended in the atmosphere. It was evident that, according to the first view, notification of phthisical patients

was unnecessary; according to the second, tubercle in dairies might be neglected. There were some also who believed that though the tubercle germ could not arise *de novo*, yet as a result of unhealthy conditions its virulence might be sometimes *de novo*. What Dr. James wrote 15 years ago he still believed in, that "you may kill off every tubercular cow, you may banish every phthisical patient, the conditions of life of men and cows remaining the same, you will have tubercular diseases back again in six months." 2. There were differences between the phthisis germ and the germ, of those other infectious diseases in that the tubercle germ having entered the body only did harm when the individual was, or got into, a lowered state of health. The individual, therefore, might never suffer from phthisis at all, or, if he did, his illness might come on at times and places when and where there were no tubercle germs in his surroundings at all. As far as directing attention to the source of his disease is concerned notification might be useless and misleading. 3. Efforts made to treat pulmonary phthisis by combating the germ in the manner in which such truly infectious diseases as rabies, diphtheria, and tetanus are treated have been found to be not only useless but disastrous. Many could remember the confident and high hopes engendered by the tuberculin treatment of Koch. It seemed to Dr. James that the same type of mind which predicted triumphant success in the case of this treatment directed to the germ was to be discerned in those who now as confidently predicted the benefits to be obtained from notification and efforts to stamp it out. It is well known that the effects of the original tuberculin treatment were disastrous. This tuberculin was now known as the "dangerous tuberculin," and its use now in the method advocated 15 years ago would render its employer liable to a charge of manslaughter. It was stated that the profession was unanimous in favour of notification. Dr. James said that this was simply not true. Everyone admitted that notification and what it entailed had advantages, but they must also acknowledge that it had weaknesses and disadvantages. Dr. James thought that if they balanced these evenly they would agree in advising that compulsory notification of pulmonary phthisis was necessary in all cases where the patient's circumstances and surroundings formed a menace to the public health. Unsparring efforts to improve the conditions of life of the people at home and at work will be certain at one and the same time to increase the resisting power of the individual against the germ and to destroy the virulence of the germ itself.—Dr. BYRON BRANWELL stated that 53 of the largest cities in America had adopted the compulsory notification of phthisis, and that the procedure was already in action in these towns. The leading American physicians were thoroughly convinced of the necessity for compulsory notification. The sources of the tubercle bacillus were from human beings or from bovine and lower animals. In practice, however, the real source was from the sputum. If they could disinfect and destroy the tubercle bacilli they should go far to eradicate phthisis.—Dr. T. F. S. CATVILL said that with the same facts as Dr. James had employed he had arrived at exactly opposite results. It was easy to stamp out tubercle in animals. In the human being the infection might be slight but then it was continuous, acting for months or even years. He thought that the great increase in the number of cases of infectious diseases was due to the greater movement of the populace now as contrasted with former periods.—Dr. GEORGE HUNTER and Dr. S. MACVIE (Chirside) also took part in the discussion, and Dr. JAMES replied.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—A meeting of this society was held on Jan. 4th, Dr. R. H. Woods (Dublin), the President, being in the chair.—Mr. Charles J. Heath showed a further series of cases illustrating the successful treatment of Chronic Suppuration of the Middle Ear without removal of the drum or ossicles or loss of hearing.—Mr. H. Clayton Fox asked wherein Mr. Heath's operation was superior to that method of Schwartz which consisted in clearing out the antrum and its environs and syringing through into the tympanum without the disadvantage of having to remove the posterior meatal wall. He expressed a fear that the adhesions left after Mr. Heath's operation would induce tinnitus at some future date and necessitate ossiculectomy.—Mr. Heath replied that trustworthy information as to the state of the

tympanic cavity could not be obtained through the intact meatus. Only after removal of the posterior meatal wall could efficient investigation of the tympanum be carried out. Herein lay the superiority of his operation to that modification of Schwartz's operation mentioned by Mr. Clayton Fox. From the information thus obtained the surgeon could decide whether the case was one which called for the complete radical operation, or one where the modification suggested by himself would suffice. The cases which he exhibited on the present occasion included, besides instances of ordinary suppuration of the middle ear, two cases of attic suppuration with perforation in Shrapnell's membrane, one case of facial paralysis, and one case in which ossiculectomy had previously been performed without remedying the suppuration. The antrum was the key to the position in nearly every case of suppurative ear disease, and if the disease in that cavity were cured the morbid changes in the attic and tympanum would disappear spontaneously.—Mr. Mayo Collier showed a case of Extensive Epithelioma of the Floor of the Mouth, beginning in the frenum linguae, which he had removed, along with the submaxillary glands, by a new method of operation.—Mr. Harold S. Barwell showed a case of Tuberculous Ulceration of the Pharynx in a male, aged 17 years. The patient was the subject of pulmonary tuberculosis in an early stage affecting both upper lobes. The ulcer manifested typical tuberculous characters; it had a flat, smooth, pale floor with edges not infiltrated. The larynx was healthy.—Mr. W. J. Chichele Nourse said that he had recently seen a case of tuberculous pharyngeal ulcer which was deep with raised edges, exuberant granulations, and marked scarring, quite like a gummatous ulcer. There was no history of syphilis, however, and a scraping from the ulcer contained tubercle bacilli.—Mr. Barwell exhibited a case of Gumma (!) of the Larynx, which was shown at the last meeting, and in which a rounded soft swelling over the right thyroid ala had been opened and the cavity curetted. On laryngoscopic examination little change was to be detected in the tumour. The external wound had healed. The microscopic appearances of the tissue removed were suggestive of carcinoma, according to Dr. Robert S. Trevor and Dr. V. H. Wyatt Wingrave.—Mr. Nourse exhibited a case of Multiple Sinusitis showing the result of Radical Operation. He said that the disease had probably begun in the left ethmoidal region and had led to symptoms of left frontal sinusitis. On opening the frontal sinus the cavity was found to be very small and packed with greyish mucus. At a later date the left antrum was radically dealt with through an opening in the canine fossa, and at this operation the ethmoidal region was cleared through the inner wall of the antrum. The result both as regards the suppuration in the nose and the external scar was excellent.—The President drew attention to the rule sometimes laid down that a complete and entire removal of the anterior frontal sinus wall was necessary to insure the success of the operation. He, however, believed that as much, and no more, of the anterior wall should be removed as would give complete access to the cavity, so that the whole of the diseased lining membrane could be removed. If that were effectually done, as he found in his cases, the sinus being left open would heal up from the bottom in from six to eight weeks. Unless the bone around the fronto-nasal duct was diseased he did not enlarge that canal.—Mr. Nourse, in reply, said that he agreed with the President as regards the removal of the anterior sinus wall but differed from him in regard to the external wound, which he was in the habit of closing, while he inserted a large drainage-tube into the infundibulum long enough to extend from the frontal sinus through the infundibulum to a little beyond the nostril so as to prevent re-infection of the sinus from the nasal cavity.—Mr. Mayo Collier read a communication dealing with a case in which a hard mass in the floor of the mouth, consisting of a large tuberculous gland with nodules of hard fibrous tissue, had been mistaken for a salivary calculus by himself and several other surgeons.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—A meeting of this society was held on Jan. 14th, Dr. J. Lindsay Steven, the President, being in the chair.—Dr. G. H. Edington showed a specimen of a Perforated Peptic Ulcer of the Jejunum occurring after Gastro-enterostomy. The patient, a male, aged 46 years, was operated on seven years previously by Dr. T. K. Dalziel for pyloric obstruction with symptoms of six years' duration, an anterior gastro-jejunostomy being performed. Five years

later Dr. Dalziel removed a gall-stone from the cystic duct. The patient remained free from all stomach symptoms after the first operation. Early in November, 1906, he was admitted to the Western Infirmary with symptoms of perforated ulcer of 25 hours' duration. Dr. Edington opened the abdomen and found a perforated ulcer of the jejunum just beyond the gastro-jejunal communication. He closed the ulcer with Lambert sutures and covered over the part with a flap of omentum. The patient, who was collapsed on admission, did not rally and death took place three hours later. The post-mortem examination showed a healed ulcer at the commencement of the duodenum with constriction of the pylorus. The gastro-jejunal opening admitted the cone to a diameter of one and a half inches. The perforation in the jejunum had occurred in a portion of an ulcer the margin of which reached to the gastro-jejunal orifice.—Dr. A. N. McGregor showed a patient who had a Rupture of the Vagina with Protrusion of Bowel which he had successfully treated by replacement and suture. The patient was a woman aged 63 years, who while engaged in carrying coals into her house experienced pain and discomfort internally. Feeling ill she took some stimulant on going to bed. She woke up in the small hours of the morning and in getting out of bed fell across a chair and sustained a blow on the perineum. Immediately thereafter blood issued from the vaginal orifice and the bowel also prolapsed through it. Three days later she called in a medical man who sent her into hospital. On admission a large mass of bowel was seen in front of the vulva protruding from the vagina, of about the size of two closed fists. The coils of intestine were matted together with fibrinous exudate and pus was present in the sulci. The loops of bowel were separated and on examination an opening in the posterior wall at the upper end of the vagina was found. An inch or so of bowel was pulled out through the opening and found not to be strangulated. The whole mass was carefully cleansed and replaced into the pouch of Douglas, the vaginal opening was stitched up, a gauze drain was inserted, and the vagina was packed with gauze. The vaginal packing was changed daily and the gauze drain was removed on the seventh day. On the fourteenth day she was allowed up and at the end of three weeks was dismissed well. The immediate cause might have been a proidentia on the first occasion and a perineal concussion in the second instance determining a rupture, or at the second accident a part of the chair might have penetrated through the vagina, but no further injury of the vulva, perineum, or vagina was noted. A vaginal examination six weeks later by Dr. J. K. Kelly revealed no abnormality save the presence of the scar. The uterus and appendages were normal but senile in character and no uterine or ovarian tumour was present. There was no history of previous vaginal or uterine disorder and the patient had had ten children normally.—Dr. McGregor showed for Dr. J. A. Adams a Fibromyoma of the Ovary removed from a patient suffering from acute intestinal obstruction. The patient was operated on five years previously on account of strangulated femoral hernia of the right side. On the present occasion a Littre's hernia of the left side and the tumour of the ovary were found. The former was relieved and the latter was removed.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 16th, Mr. E. Powell, the President, being in the chair.—Mr. A. R. Anderson showed the Uterus with Contained Fœtus and Placenta of a primipara, aged 35 years, the subject of fibromyoma necessitating hysterectomy at four to four and a half months. Recovery had been rapid and uneventful.—Mr. Anderson also showed a specimen of true Papilloma removed from the posterior part of the bladder floor in a man, aged 36 years. It was a large mushroom growth, pedunculated, and had several times caused retention, there being also and had several times caused retention, there being also cystitis and hæmaturia. To prevent an undue enlargement of the suprapubic incision the growth had been removed in four pieces with scissors and the patient had made a complete recovery in every way.—Dr. F. H. Jacob read a paper on the Diagnosis and Treatment of some Diseases of the Skin. In tracing the diagnostic points of lupus special stress was laid on the daylight appearance of the yellowish, translucent, apple-jelly-like nodules, which did not disappear on pressure with glass. On the hands and in the similar regions the typical nodules might be masked by the occurrence of a chronic inflammatory thickening. A case of

tertiary syphilis was related in a man who had been under treatment for lupus for five years by different practitioners without success. In the later stages the appearance of a large V-shaped ulcer dividing the whole thickness of the upper lip, as well as some plaques with ill defined margins on the face, made a correct diagnosis easier, and suitable anti-syphilitic treatment brought about a cure. Under the head of treatment Dr. Jacob pointed out that x rays gave good results with the least expenditure of time. The resulting scar was not always slightly and was liable to produce telangiectases, for which pure carbolic acid was often the most efficient application. Referring to the typical appearance of lupus on the gums and the punched-out ulcers it gave rise to on the hard palate its behaviour in the latter position was contrasted with similar ulcers due to syphilis, in that lupus, although a tuberculo-sis, never caused ulceration in bone. What were known as tuberculous gummata of the skin constituted a serious affection and of three such cases in children under his care all had subsequently succumbed to meningitis. The erythematous variety of lupus was often readily cured by the full doses of quinine recommended by Payne. The sebaceous variety was more troublesome but would yield to a single burning with x rays. The framboesial variety of syphilis was next described; it was amenable to antisyphilitic treatment if pushed. The distinctions between psoriasis, syphilitic psoriasis, and seborrhœa were then touched on and attention drawn to Whitfield's observation as to the frequent presence of the bottle bacillus in the last mentioned. Photographs were then shown and described of several interesting skin conditions, such as a tuberculous warty condition successfully treated by x rays; recurring raised vaccination marks; an elderly woman with papules at the nose tip diagnosed as acne necroticans serpiginosa; a baby with well marked urticaria pigmentosa; ringworm of the nails; and an epileptic girl of deficient intelligence with adenoma sebaceum on the face and pendulous adenomata on the back.—The paper was discussed by the President, Mr. A. R. Tweedie, Dr. J. S. Bolton, and Dr. W. Hunter, and Dr. Jacob replied.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 11th, Dr. John Brown being in the chair.—Dr. Leslie Buchanan showed two cases of Birth Injury of the Cornea. Both were typical illustrations of the results in later life of the rupture of the posterior surface of the cornea in consequence of extreme pressure upon the head of the child by instrumental delivery. Five cases of this kind had now been seen by him within three years. The condition was very easily overlooked. Two or more faintly marked curved lines might be seen crossing the cornea, usually in a nearly vertical direction, inclosing a space shaped like a broad barrel-stave. In any case where a high degree of astigmatism (usually myopia) was found in one eye only, the characteristic lines of refraction opacity should be looked for, either with the ophthalmoscope or by focal illumination, and the history of the birth inquired into.—Dr. Buchanan also read notes of a case of Metastatic Ophthalmitis which had occurred in the course of a case of pneumonia. The eye affection first showed itself on the fifteenth day of the disease, after the crisis, and at the same time the temperature again rose and became remittent. No cardiac murmur could be discovered. The eye was totally destroyed. The patient ultimately died and a necropsy showed that there had been malignant endocarditis. The pneumococcus was found both in the eye and in the splenic pulp.—Dr. W. F. Somerville read a paper on the Treatment of Neurasthenia. He emphasised the necessity for complete isolation in a neurasthenic home as opposed to an ordinary nursing home. Patients were kept in bed for three weeks and then allowed up. They were given a very full diet, including from 20 to 80 ounces of milk per diem. General massage, medical exercises, and the high-frequency current were also employed. The daily routine was so arranged that there was no time for dullness. During the last two or three weeks of their stay they went out shopping and this made the change of returning to their homes less abrupt.—Dr. W. S. Syme showed: 1. Two cases of Ossiculotomy (or patients in whom the operation of Ossiculotomy had been performed. The operation was limited to the tympanum indicated where the disease was limited to the ossicles, the and ossicles or attic. The amount of discharge, the position of the perforation, and information obtained by the use of the probe were the chief points in determining such limitations

of the disease. 2. A patient with Right Recurrent Laryngeal Paralysis, thought to be due to an old-standing tuberculous lesion at the right apex.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on Jan. 4th, Dr. J. B. Ball, the President, being in the chair.—Dr. P. Watson Williams showed stereoscopic skiagraphs of the Nasal Accessory Sinuses.—Dr. St. Clair Thomson and Dr. Herbert Tilley exhibited specimens of Cartilage and Bone removed by means of Killian's submucous resection operation for the correction of deviations of the septum. A discussion followed on the relative merits of local and general anaesthesia for this operation; on this point opinions appeared to be divided.—Dr. W. Jobson Horne exhibited macroscopic preparations illustrating Cystic Disease of the Larynx and a condition simulating cystoma.—Dr. W. H. Kelson showed a woman, aged 65 years, with a Circumscribed Tumour of the Palate of about eight weeks' duration. There was a difference of opinion as to its nature, the diagnosis being a fibro-adenoma or an endothelioma. It was generally agreed that it should be removed.—Dr. Kelson also showed a patient with Ulceration of the Epiglottis and of the Base of the Tongue which was regarded as malignant disease and inoperable.—Mr. P. R. W. de Santi showed a case of Tertiary Syphilitic Laryngitis for opinion as regards treatment.—Dr. A. Lieven recommended tracheotomy to keep the parts at rest; if it were not done now it would have to be done later to overcome the contraction of the glottis; he advised injections of calomel, using 1 part of calomel in 10 of vasoline, a new preparation of paraffin which was the least irritating vehicle he knew. A very small dose should be given at first as the patient might be intolerant of mercury.—The President showed a case of Laryngeal Disease presenting Difficulties of Diagnosis. Opinions were in favour of it being due to syphilis.—Dr. O. A. B. Horsford showed a patient with Considerable Enlargement of the Cervical Glands following Removal of a Tonsil. The diagnosis rested between primary chancre of the tonsil, malignant disease, and deep suppuration in the neck. It was advised that anti-syphilitic treatment should be used before incising the neck. Dr. Horsford was asked to report to the society the subsequent history of the case.—On behalf of Dr. G. O. Cathcart, Dr. Jobson Horne showed the specimen from a case of Fibroma of the Larynx in a patient present at the last meeting of the society. When the patient was exhibited there was a general consensus of opinion that the tumour, which occupied the left arytenoid region, was a cystoma. It was subsequently found to be a solid tumour which had to be removed through an external incision.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Manchester on Jan. 18th, Mr. R. Favell (Sheffield) being in the chair.—Dr. E. O. Croft (Leeds) was elected President. Dr. J. H. Willett (Liverpool) secretary, and Dr. W. E. Walls (Manchester) treasurer for 1907.—Mr. Favell showed a large Hypernephroma of the Left Kidney which occupied the pelvis and lower portion of the abdomen, and was successfully removed by the abdominal route.—Dr. J. B. Heilier (Leeds) showed a Fibroid Polypus of the Cervical Canal which was of such size that it completely filled the vagina and was so irregular in form that it closely simulated a "candleflower excrescence" of the cervix.—Dr. A. J. Wallace (Liverpool) showed a Uterus removed for Cancer of the Cervix by the abdominal route with extensive dissection of the pelvic glands and connective tissue. The obturator gland was shown to be much enlarged by secondary deposits, as were also glands dissected off the iliac vessels. Dr. Wallace regarded vaginal hysterectomy as merely palliative. He had done the extensive abdominal operation in nearly 20 cases with a mortality of under 30 per cent. In fat subjects the operation was dangerous and prolonged, but in thin patients it did not appear to be attended by undue risk.—Dr. D. Lloyd Roberts (Manchester) showed a Fibroid 13 inches in diameter and weighing over 32 pounds. It was removed from a multiparous widow, 44 years of age, who had been aware of its presence for 14 years. It finally produced pressure symptoms, menorrhagia, and metrorrhagia. The capsule was incised and the growth was enucleated as a preliminary to the removal of the uterus at the level of the internal os. Recovery was uneventful.—Mr. E. Stanmore Bishop (Manchester) showed a specimen illustrating the advantages of Anterior Vaginal Hysterectomy for the

Removal of Certain Submucous Fibroids; also an example of Ectopic Gestation in which the symptoms and history suggested gonorrhoeal pyosalpinx rather than tubal pregnancy.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Jan. 18th, Dr. J. R. T. Conner, the President, being in the chair.—Mr. Peter L. Daniel gave a demonstration on Common Surgical Affections frequently met with in Out-patients. He said that in a child any injury of the elbow-joint causing pain was most probably a fracture. A frequent sequel to treatment was ankylosis, so the prognosis must be guarded. In treatment of fracture of the epicondyle the elbow should be flexed and put up in an anterior angular or a posterior angular splint, which could be readily made of Gooch's splinting. The arm ought to be kept in position for ten days, after which the child should be allowed to perform active movements. Injuries about the elbow-joint were difficult to diagnose, so they ought to be examined with the x rays and at once put up in the best position, whether in flexion or extension. Movement ought to be practised in a few days as less ankylosis was thus got. Collie's fracture was reduced by employing extension and adduction and by applying splints, which should be taken off in 24 hours, and all the fingers should be moved to free the tendons and so prevent adhesions. The splints ought to be discarded in a week. Leucoplakia in syphilitic patients was wholly caused by oral sepsis. Bad teeth ought to be removed and an antiseptic mouth wash should be used after every meal. Pruritus and entirely depended on moisture and germs in cases of piles, leucorrhoea, fissure, abscess, general colitis, &c. The parts should be carefully cleansed after defecation and frequently mopped with a glycerine, spirit, and carbolic lotion. Chronic ulcer of the leg should be treated by elevating the leg and cleansing the ulcer with an unirritating lotion and by the application of one inch wide strips of diachylon plaster from two inches below to two inches above the ulcer, laid on the leg without pulling. The limb should be bandaged from the toes to the knee and the dressing changed at the end of 24 hours.

MANCHESTER PATHOLOGICAL SOCIETY.—A laboratory meeting of this society was held in the pathological laboratory of the University of Manchester on Jan. 16th. The following demonstrations took place:—Dr. W. B. Atterton: Some naked-eye specimens.—Dr. E. M. Brockbank: Blood Plates.—Dr. W. J. S. Bythell: Photo-micrographs in natural colours.—Professor S. Delépine and Dr. A. Sellers: (1) Hydatid Cyst of the Brain of a child; (2) Bacterial Necrosis of the Liver of a calf; (3) Botryomycosis in the horse; (4) specimens illustrating the Bacteriology of Plague; (5) specimens illustrating the Comparative Pathology of Tuberculosis; and (6) method of cutting sections by the Delépine freezing microtome.—Dr. Fennell: Traumatic Affections of the Cervical Vertebrae.—Mr. F. R. Howson: Specimens of physiological interest.—Dr. G. E. Loveday and Dr. A. Ramsbottom: Determination of the Opsonic Index.—Dr. W. Mair and Dr. C. Powell White: Primary Carcinoma of the Liver of Suprarenal Origin.—Dr. F. Craven Moore: Endothelioma of the Stomach.—Dr. D. Orr and Dr. R. G. Rows: Lesions of the Central Nervous System.—Dr. Parker: Pathological Lesions of the Eye.—Mr. L. Savatard: Microscopical specimens of skin diseases.—Dr. W. F. Shaw: Chronic Metritis.—Professor J. Lorrain Smith: Fat staining by aniline dyes.—Mr. F. A. Southam: Cystine Calculi.—Dr. Powell White: Fat Crystals and Fat Emboli.—Dr. Powell White and Mr. Roberts: Intracystic Fibro-adenoma of the Breast.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At the Rowton Club, Wick, Gloucestershire, on Jan. 15th, Mr. Henry Hugh Williams, L.R.C.P., L.R.C.S. Edin., was entertained at dinner and afterwards the chairman, the Rev. H. Tomkins, vicar of Wick, on behalf of the subscribers, presented him with a silver rose bowl mounted on an ebony plinth, bearing the following inscription: "Presented to Henry Hugh Williams by many grateful friends and patients on his retirement from practice in Wick and the neighbourhood, January, 1907."—The members of the Wigan Medical Society have presented Mr. J. Blair, M.D., M.Ch. R.U.I., with a sugar basin in the form of a silver cradle on the occasion of the birth of a son during his presidency in 1905.

Reviews and Notices of Books.

Hermann von Helmholtz. By LEO KOENIGSBERGER. Translated by FRANCES A. WELBY, with a preface by Lord KELVIN. Oxford: Clarendon Press. 1906. Pp. 440. Price 16s. net.

THE story of Helmholtz's life rivals in interest any previous biography of scientific men which it has been our lot and our good fortune to read. His career was pregnant with scientific discoveries which have been not merely of academic interest but of importance to the world's practical affairs, inasmuch as they have contributed in many directions to the welfare of all peoples. In this connexion may be mentioned one branch of study in which Helmholtz's researches and ideas were fruitful. He it was who, in Lord Kelvin's words in the preface to this volume, gave to Hertz the inspiration to find experimental proof of Maxwell's electric waves. Not long afterwards the first practical demonstration was given of progressive electric waves and of stationary waves in air, and therefore inferentially, in the ether undisturbed by ponderable matter. The result has since been the achievement of wireless telegraphy. Helmholtz was, as we are reminded by this biography, a medical officer in the Prussian army for five years, was teacher of anatomy in the Academy of Arts in Berlin for one year, was professor of pathology and physiology in Königsberg for six years, was professor of anatomy in Bonn for three years, professor of physiology in Heidelberg for 13 years, and professor of physics in the University of Berlin for about 20 years. What wonder, then, that the story of his life is full of interest and that his work so greatly enriched our knowledge of physiological facts. To medical readers in particular perhaps the story of his life while professor of physiology at Königsberg, 1849-55, affords one of the most interesting chapters. It was here during the preparation of his lectures that he hit upon the invention of the ophthalmoscope and then on the method of measuring the velocity of nervous impulses. In a letter to his father in December, 1850, he wrote: "I have made a discovery during my lectures on the physiology of the sense organs which may be of the utmost importance in ophthalmology. It was so obvious, requiring, moreover, no knowledge beyond the optics I learned at the gymnasium, that it seems almost ludicrous that I and others should have been so slow as not to see it. It is, namely, a combination of glasses by means of which it is possible to illuminate the dark background of the eye through the pupil, without employing any dazzling light, and to obtain a view of all the elements of the retina at once, more exactly than one can see the external parts of the eye without magnification, because the transparent media of the eye act like a lens with a magnifying power of 20. The blood-vessels are displayed in the neatest way with the branching arteries and veins, the entrance of the optic nerve into the eye, &c. Till now a whole series of most important eye diseases known collectively as black cataract have been *terra incognita*, because the changes in the eye were practically unknown both during life and, generally speaking, after death. My discovery makes the minute investigation of the internal structures of the eye a possibility." Subsequently "this very precious egg of Columbus" was announced at a meeting of the Physical Society, Berlin, as Helmholtz's property and a new and improved instrument soon replaced his "pasteboard affair." Helmholtz confessed that he might not have persevered save for his conviction that it must succeed—a feeling which has been the experience of the founder of many a brilliant discovery—but after about eight days he "had the great joy of being the first to see a living human retina" exposed

before him! Physics, however, as his many and valuable papers on colour, sound, meteorology, cohesion, and electrodynamics bear witness, was Helmholtz's bent and all serious students of that branch of science recognise what an enormous loss the world of science and progress sustained by the death of Helmholtz in 1894. "His early death," said du Bois Reymond, "which removed him in the midst of his full working powers was felt not merely as an irreparable loss to science but as a national misfortune."

The book before us is a well-written and enthralling story of the career of a remarkable scientific character. Not a chapter, not a page, is dull reading to those interested in the developments and working of a scientific mind, the activities of which had achieved such brilliant results. The story, too, of his domestic relationships is full of charming episodes. It is not difficult to realise that the writer of this biography was in close personal touch with the subject of his sketch, and further, it is obvious that he possessed a clear scientific view of Helmholtz's aims, studies, and results. For the English translation we have nothing to express but praise, and to the translator and the Oxford University Press we may say, what we feel English scientific men generally will say when they have read this charming biography, that we are grateful for a very valuable and interesting account of a very valuable and interesting life.

Recent Advances in the Physiology of Digestion. By E. H. STARLING, M.D. Lond., F.R.S. With 12 illustrations. London: A. Constable and Co., Limited. 1906. Pp. 156. Price 6s. net.

THE Mercers' Company gave a donation in aid of the work of the Physiological Department at University College, London, and these lectures are the first course of Mercers' Company lectures. The masterly series of researches of Pawlow on digestion and the digestive gland have led to a great development in this branch of physiology but we still require a better knowledge of the physical and chemical conditions which determine the digestive changes in the foodstuffs themselves.

The first two lectures—dealing with the action of ferments—approach a subject which must play a great part in all our future conceptions of intracellular mechanism—i.e., the study of the chemical and physical changes in colloidal and capillary systems, where the modification of physical conditions occurring at surfaces determines changes of another order. There is the second important starting point that the pancreas is excited to secrete by the despatch of a chemical messenger, or hormone, formed in the gut and sent to the reacting gland through the blood stream.

The third lecture gives an excellent account of the secretion of saliva, of course including the now well-known results of Pawlow's experiments on dogs with the ducts of the salivary glands made to open on the exterior of the cheek, a method which was first used by de Graaf. The author does not accept Heidenhain's view as to salivary secretory nerves, but regards the glands as supplied by one kind of fibre, namely, secretory, in addition to the fibres—i.e., vaso-constrictor and vaso-dilator—which exercise their main influence on the blood-vessels of the gland. It would have been convenient had the date—1851—of C. Ludwig's have been convenient had the date—1851—of C. Ludwig's great discovery been stated—viz., the impossibility of explaining the process of secretion as in any way determined by the blood pressure.

Digestion in the stomach is the subject of the fourth lecture. Here again there is, of necessity, a full account of Pawlow's work, and following on the brilliant discovery of secretin by Starling and Bayliss there is an account of the discovery by Ekins of a gastric secretin which is formed in that part of the stomach where the process of absorption is most pronounced—i.e., in the pyloric region. Thus it

appears that the normal gastric secretion is due to the co-operation of two factors—the first and most important is the nervous secretion, determined through the vagus nerves, and the second is chemical.

The fifth, sixth, and seventh lectures deal with pancreatic juice, the properties of its secretin, and changes in the pancreas during secretion. These lectures embrace a full account of the work of the older observers, but their special interest centres round secretin and the large part played by chemical messengers, or hormones, in exciting pancreatic secretion. The author, in treating of the islets of Langerhans, states that no evidence exists in support of the notion that the islets are organs for the production of an internal secretion and he speaks of the "equally unknown anti-diabetic function of the pancreas." The islets of Langerhans are not independent structures of separate origin but are formed, as shown by Dale and others, by certain definite changes in the arrangements and properties of the cells of the ordinary secreting tissue.

The eighth lecture on the bile is a short one. The ninth is devoted to intestinal juice and the last largely to the work of Starling and Bayliss on the movements of the intestine.

We cordially commend the study of these excellent, thoughtful, and suggestive lectures to practitioners of medicine and also to students of medicine preparing for the higher examinations.

Local Anæsthesia in General Surgery. By J. W. STRETHERS, M.B. Edin., F.R.C.S. Edin. Edinburgh: W. Green and Sons. 1906. Pp. 156, with illustrations.

THIS small book provides a clear and concisely written account of the various methods of procuring local anæsthesia. Its author is no immoderate upholder of the use of local as opposed to general anæsthetics and, in fact, appears generally to regard them as a substitute in cases where general anæsthetics are not advisable. There is, however, a wide field of minor surgery in which in many instances local is to be preferred to general anæsthesia. How best to obtain this anæsthesia Mr. Strethers's book explains very well. The various available drugs are described and the advantages of cocaine over the others are upheld provided that proper regard is paid to the question of the strength of the solution. The author thinks that $\frac{1}{2}$ per cent. is the maximum strength that should be used for ordinary subcutaneous injection. He finds that reactionary pain is common. When a tourniquet is used to enhance the anæsthetic effect this pain though more delayed in its onset is more severe, may last from five to ten hours, and may require the administration of morphine. The methods of infiltration anæsthesia are well described and illustrative cases in which various operations have been performed with the assistance of this form of anæsthesia are given in detail. A short chapter on spinal anæsthesia concludes the work.

The Cathedrals of England and Wales. By T. FRANCIS BUMPUS. Third series. London: T. Werner Laurie. 1906. Pp. 328. Price 6s. net.

THE first cathedral dealt with in this series is Lichfield, the motto of whose seventeenth-century bishop, Hackett, "Serve God and be cheerful," might, by the way, well be commended to the pessimists of this dyspeptic age. In every English cathedral is enshrined the memory of one or more great names, and accordingly in the chapter on Lichfield the author gives us appropriate references from Boswell and other sources to Dr. Johnson whose kindness of heart (notably in the case of that "obscure practitioner in physick amongst the lower people," as Boswell quaintly describes Mr. Robert Levett, whom the great author so

generously helped) is too often forgotten in our admiration of his genius. Gloucester, the next in order in the volume, is associated with the name of that great English musician, Dr. S. S. Wesley, of whom an interesting account is given. Rochester is so inseparably associated with Dickens that the author has prefaced his chapter on that fame with a lengthy extract from the great novelist's last and, alas, unfinished work (which is almost exclusively occupied with the cathedral), "Edwin Drood," and in addition he gives another extract in the text. Oxford, "the home of lost causes," as Matthew Arnold calls it, holds so many great names that our space will not allow us even to enumerate them but here again the author has produced a full and interesting chapter.

It must not be supposed, however, that although it deals with weighty matters the book is heavy, for, mixed up with exhaustive descriptions, architectural, historical, musical, and biographical, are anecdotes in a lighter vein, such as that relating to Dr. Corfe, sometime organist of Oxford Cathedral, who so rarely changed his stops during the service that the undergraduates called the particular quality of tone produced the "Corfe-mixture." The remaining cathedrals in the series are Carlisle, Llandaff, Bangor, St. David's, St. Albans, Ripon, Manchester, Truro, Southwell, Newcastle, Wakefield, Liverpool, Birmingham, and Southwark.

The full-page plates, 32 in number, are excellent and the volume will be found to be as interesting as it is instructive.

Elements of Practical Medicine. By ALFRED H. CARTER, M.D. Lond., M.Sc. Birm. Ninth edition. London: H. K. Lewis. 1906. Pp. 614. Price 10s. 6d.

THE fact that a ninth edition of this well-known and popular work has been demanded is of itself a proof that it has accomplished the object for which it was written—namely, that of an elementary introduction to the study of medicine. In the work before us the text has been carefully revised throughout, many sections having been entirely rewritten, and a few necessary additions have been made, bringing the contents up to date. The author has availed himself of the help of Dr. A. Stanley Barnes in the chapters on Pathology and Nervous Diseases, and of Dr. A. Douglas Heath of the Skin Department in the Birmingham General Hospital in the section on Diseases of the Skin.

In a work so well known criticism can scarcely find a place and such as we offer has merely the object of making the next edition still more complete. Amongst certain methods of treatment we find no mention of that of dysentery by izzal which has been so successfully carried out in India by Vaughan. Excellent results, again, in the treatment of blackwater fever have accrued from cassia Bearesna. Acute pneumonia is considered amongst the diseases of the lungs; surely its place rather is amongst the specific infective diseases, especially as the author himself describes it as one of these. But in truth the scope and treatment of the work are so excellent as an elementary text-book that we need not do more than heartily recommend it as a volume which the student will find helpful in every way at the commencement of his medical career.

LIBRARY TABLE.

The Elements of the Practice of Comparative Medicine, together with the Records of Some Cases. By FRANK TOWNEND BARTON, M.R.C.V.S., and GEORGE GREENSWELL, M.A. Oxon., L.R.C.P. Edin. London: Everett and Co. Pp. 240. Price 5s. net.—In presenting this volume to the students of the medical and veterinary professions the authors say that they have endeavoured to give an outline

of the principal clinical features of some of the diseases that are communicable from the lower to the higher animals, without entering into the details found in the text-books of human and veterinary medicine. Mr. Barton and Mr. Gresswell have broken ground, so to speak, in a new country, but it appears to us as if they have rushed into print without duly considering the best way of writing such a book or weighing all the evidence of the subject matter. We find also misspelt words, such, for instance, as "pruritis" at p. 208; such mistakes are probably due to bad proof reading. For poor and faulty description we may refer to the section on Vaccinia or Cow-pox, of the protective virtues of which the authors are perhaps uncertain. How can the presence of a varicocele favour tuberculosis? The authors say that it does so, "probably by fanning, so to speak, an already lit fire."

The "Ideal" Medical Diary and Visiting List. London: Langley and Sons, Easton Printing Works, George-street, N.W.—This diary, of which we have received two samples, one wallet being of morocco, and the other of imitation morocco, just fills the breast pocket of a coat. On opening the wallets, which are fastened with spring buttons, the contents are seen to be divided into two distinct portions. To the left is a diary and visiting list; to the right is a manifolding prescription book. Each wallet has an inside pocket and a penol. In the real morocco wallet the diary section is detachable; in the imitation morocco wallet the diary is fixed. In each the prescription book is removeable. The diary contains a calendar for three years, 1906, 1907, and 1908, four double pages or "openings" for obstetric engagements, and the "general visiting list" with an "opening" for each week of the year, containing on each page columns for names and addresses, and to the right thereof seven narrow columns headed with the days of the week and dates. In this connexion, there are signs suggested for use in the "Visiting List," such as a cross with two dots for two visits made, and a cross with three dots for three visits made, and so on. At the end of this section follow a dozen pages for memoranda, two pages for nurses' addresses, eight pages for patients' and general addresses, and four pages for a record of vaccinations. All these are ruled into proper columns. Then, to close the section, is an obstetric table. The second and distinct section consists of a prescription book comprising 50 fixed tissue and 50 detachable thick pages, and a carbon sheet for manifolding, placed between cards with a lustrous metallic surface. The year is printed in gilt figures, both on the exterior side of the wallets, and at the foot of the narrow back of the books so that the years may be read when the books are packed on a bookshelf. Each diary, we find, weighs half a pound. The prices of the diaries are respectively 7s. 6d. and 5s. and the prices of the refills are, for the diary, 3s. 6d.; and for the prescription book, 6d. The real morocco wallet is advertised as being "available for refills for subsequent years." In that case might it not be as well in the case of this book to omit the gilt figures which denote the year? The whole book, which we are told has been made "as suggested by a member of the profession," seems quite businesslike and will appeal to all those who value method with its labour-saving, time-saving, and worry-saving consequences.

Wellcome's Medical Diary and Visiting List, 1907.—We have received from Messrs. Burroughs, Wellcome, and Co. a copy of their medical diary consisting of 152 pages, comprising sections for accounts asked for or sent, nurses' addresses, patients' and general addresses, cash account, diary, visiting list, infectious cases notified, memoranda, obstetric engagements, patients certified under the Lunacy Act, and vaccinations. There is also a column of signs suggested for use in the visiting list. In addition there are

many pages devoted to useful therapeutic notes, a posological table, legal information, diet tables, weights and measures, medical and other formulae, and postal information. There is also a parchment strip on the inside back cover for memoranda, the pencil marks made on which can be erased with a damp cloth. The whole diary and additional matter are contained in a leather wallet, with an inside pocket and pencil and a bookmark. We find that it weighs 11 ounces but there is certainly plenty of value in a small compass.

Whitaker's Almanack for 1907. By JOSEPH WHITAKER F.S.A. Pp. 792. Price 2s. 6d. *Whitaker's Peerage for 1907.* Pp. 737. Price 2s. 6d. London: Whitaker and Sons.—We can only repeat monotonous praise for these two incomparable books of reference. They are both as good as ever they were, if not better. One new feature of the Almanack is an account of the Growth of Travelling Facilities in London. The writer of this article draws attention to the fact, which must have been noticed by any observant person, that so far from increased facilities reducing traffic in the streets they only increase it. London, in fact, was not built for modern "facilities of travelling," and until either an earthquake or a Haussman comes to work wholesale removals the old cramped streets will remain congested. The "Peerage," which is also a baronetage, knightage, and companionship, contains an enormous amount of information in a small compass, and the two volumes are indispensable to everyone who desires information about the world in which he lives.

Who's Who? 1907. Pp. 1958. Price 10s. net. *Who's Who Year-book, 1907.* Price 1s. net. London: A. and C. Black.—The issue of "Who's Who?" for the current year is larger by some 80 pages than that of 1906 and we note that the price has been increased from 7s. 6d. to 10s. No explanation is given in the "advertisement" of this somewhat large increase in price, but all the same "Who's Who?" together with its companion "Year Book," remains a most useful book of reference. We ourselves find it a constant help, and the detailed information in its pages is, we know, often drawn upon by our lay contemporaries. No medical man, however, can understand upon what system some names are excluded and some included, while the amount of space devoted to quite unimportant individuals is in some instances comic.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. LANGLEY, Sc.D., F.R.S. Vol. XXXV. Nos. 1 and 2. Dec. 29th, 1906. London: C. F. Clay. Pp. 162. Price 10s.—The contents of this part are: 1. On the Movements of the Uterus, by Arthur R. Onshny, M.D. Aberd., with 12 figures in the text. Dr. Onshny's observations were made upon rabbits, cats, and bitches. The abdomen was in each instance opened whilst the body of the animal was immersed in normal saline solution at 38° C., care being taken that there was no exposure to the air. The hypogastric nerve was tied and cut. In virgin cats and rabbits the uterine often remained motionless for a long time, but after manipulation or after exposure to the air rhythmic contractions were developed. He thinks that in the intact animal movements may probably be absent altogether. In animals in heat and during and after pregnancy spontaneous movements are generally present. The spontaneous movements of the longitudinal fibres are slow, the intervals between successive contractions being about from 15 to 60 seconds but sometimes as much as 10 or 12 minutes, varying much in strength. The contractions in different parts of the uterus often bore no relation to one another. The contractions of the circular fibres resembled

these of the longitudinal fibres and occurred independently of them. Mechanical or electric stimulation of the uterus causes a powerful contraction lasting from 10 to 30 seconds. Powerful contractions can be excited by stimulation of the hypogastric nerve. Anæmia of the organ artificially induced caused slow and weak contractions. The effects of various drugs, nicotine, pilocarpine, atropine, adrenalin, and quinine, are given. Aloin injected intravenously induced immediate contraction; alcohol had little or no effect. 2. On the Presence of Lactase in the Intestines of Animals and on the Adaptation of the Intestine to Lactose, by R. H. Aders Plimmer, D.Sc. 3. The Hematology of Carbon Monoxide Poisoning, by G. G. Nasmith, M.A., Ph.D. (Toronto), and D. A. L. Graham, M.B. (Toronto). The authors of this article show that the poisonous effect of carbon monoxide is due to its prevention of the normal combination of oxygen with hæmoglobin, but if the animal (guinea-pig) be kept in a dilute mixture of carbon monoxide with air an effort is made by the system to overcome the toxic influence of the gas by the production of a greatly increased number of erythrocytes. 4. The Conditions of Tissue Respiration, by H. M. Vernon. 5. The Importance of Individual Amino-acids in Metabolism: Observations on the Effect of adding Tryptophan to a Dietary in which Zein is the Sole Nitrogenous Constituent, by Edith G. Wilcock, Fellow of Newnham College, Cambridge, and F. Gosland Hopkins, F.R.S. The authors of this article find that a dietary containing zein as its only nitrogenous constituent is unable to maintain growth in young mice and the addition of tryptophan, an amino-acid absent from the decomposition products of zein, does not make it capable of maintaining growth though it greatly prolongs the survival and promotes the well-being of such animals, probably by constituting the precursor of some specific hormone. 6. On the Optimal Electric Stimuli of Muscle and Nerve, by Keith Lucas, Fellow of Trinity College, Cambridge. 7. Experimental Lymphocytosis, by W. Henwood Harvey, M.B. Tor. Dr. Harvey finds that a leucocytosis follows immediately upon the injection of pilocarpine, muscarine, or barium chloride. This effect is of purely mechanical origin and is due to contraction of the plain muscle element in the spleen and lymphatic glands. It may be inhibited by atropine. 8. On Methods supposed to Localise Phosphorus in Cells, by F. H. Scott, Ph.D., M.B. 9. On Diurnal and Nocturnal Variations in the Excretion of Uric Acid, by J. B. Leathes. 10. Experiments on the Isolated Mammalian Heart to show the Relation of the Inorganic Salts to the Action of the Accelerator and Inhibitory Nerves, by W. H. Howell and W. W. Duke. 11. Observations on Human Chyle, by J. Molyneux Hamill, M.B. Cantab. An average sample, obtained from a fistulous passage connecting the thoracic duct with an opening in the right groin, contained 3.87 grammes total solids per 100 cubic centimetres of chyle, comprising 0.83 ash; fat, from 1.344 grammes to a much larger proportion; total nitrogen, 0.264 gramme; lecithin, equal to 4.204 grammes per 100 grammes of ether extract; and cholesterol, equal to 5.2 grammes in the same. This number also contains the proceedings of the Physiological Society at the meetings held on Oct. 20th and Nov. 17th, 1906.

Man.—In the January number of *Man* M. E. Cartailhac publishes in French an account of the discovery of a great many (about 80) representations of human hands on the sides of a cavern at Gargas in the Hautes-Pyrénées. The work is supposed to be of the Palæolithic age. The process employed was such that the pigment lies outside the contour of the hand, and M. Cartailhac states that Australian aborigines now produce such designs by holding the hand against a flat surface and blowing a coloured powder over it, so that on removal of the hand an outline of it remains on the surface.

New Inventions.

A MODIFIED URETHRAL SYRINGE.

THE accompanying illustration explains the nature of the syringe. It consists of two parts—a Guyon syringe and a catheter shaped like a bladder sound. The syringe is used for applying local applications to chronically inflamed patches of the urethra. The advantages over the ordinary acorn-headed catheter are the following—greater accuracy in localising the inflamed patch is obtained by means of the beak; the difficulty of introducing an instrument through a small meatus which is capable of putting the urethra on the stretch while the application is made is overcome. A further advantage is that after the application has been applied the inflamed patch can be massaged with the beak of the syringe, which greatly aids the efficacy of the application. The Guyon syringe insures great accuracy of the quantity of the solution applied. The barrel of the syringe is six and a half inches long, and the prostatic urethra can be reached if necessary. The instrument is manufactured of silver and was made to my design by the Holborn Surgical Instrument Company.

FROM

THE LANCET, SATURDAY, Jan. 24th, 1829.

FOREIGN DEPARTMENT.

TREATMENT OF PHTHISIS BY SMOKING BELLADONNA.

PROFESSOR CARVELLIER has lately used the belladonna in phthisis with great success, in the following manner: the fresh leaves were infused in a strong solution of opium, and then dried up like tobacco; the patients began by smoking two pipes a day, and the quantity was gradually increased to six pipes. In several cases of confirmed phthisis the cough became less frequent and violent, the pain and irritation of the larynx subsided, the dyspnoea disappeared, the expectoration diminished, and became less troublesome, the profuse nocturnal sweats, the heat and febrile excitement, became less, and the disease seemed to be completely arrested.—*Nouv. Bibl. Médic.*

SINGULAR ACTION OF ARSENIC ACID ON SEVERAL SORTS OF SUGAR.

A SOLUTION of the arsenic acid and common sugar being mixed, the fluid, after a few hours, assumes a beautiful purple colour, resembling that of raspberry syrup; if instead of common sugar that of starch is used, the same colour, but somewhat brighter, is produced; the sugar of milk assumes a reddish brown colour; manna becomes of a brick colour; diabetic sugar and the saccharine principle of oil, as well as gum and pure starch, are not changed at all by the arsenic acid. Caustic potash and ammonia, have no power of destroying the colour of the above mentioned liquids; nitric and muriatic acids render it brighter; sulphuric acid changes it into a dark brown colour.—*Schneigger's Jahrbücher.*

THE LANCET.

LONDON: SATURDAY, JANUARY 26, 1907.

The Hospital Funds and the Medical Profession.

THE hospitals of London, the great medical charities of the metropolis, struggling to maintain their efficiency in an age of unprecedented scientific and social development, and to meet the demands upon their resources caused by the rapid growth of urban population, have received during the latter portion of the last century and the beginning of the present century invaluable assistance from funds organised for the purpose of collecting and distributing among them the contributions of the benevolent. Very large sums of money have been placed at the disposal of the hospital committees by these funds and in every year through their aid thousands of the poor and suffering have had medical and surgical relief which otherwise it would have been impossible for the hospitals to afford. And if in the past those controlling such funds as King Edward's Hospital Fund for London, the Metropolitan Hospital Sunday Fund, and the Hospital Saturday Fund, have earned the gratitude of their fellow citizens, they have no reason to believe that in the future their efforts and those of their successors will be less effective or less gratefully received. Indeed, there seems to be every reason to suppose that the confidence inspired by well-directed charitable organisations will cause in the future steady and substantial augmentation of the incomes of these funds, because they have been administered with care and discretion in the past.

In the circumstances it is not surprising that those responsible for the management of such funds in two instances—that of King Edward's Hospital Fund for London and the Metropolitan Hospital Sunday Fund—should be seeking to establish themselves and the important charitable movements which they represent upon definitely ordered and permanent foundations. The manner in which they propose to do so is a matter of considerable interest to the benevolent public, and no less so to the medical profession which, during the period of the existence of these great funds—as for years, or, indeed, centuries, before they came into being—has given in charity that medical and surgical treatment for the exercise of which the money of benevolent laymen has provided and maintained the hospitals. We do not of course ignore the pecuniary gifts and bequests to hospitals made by the medical profession, but, speaking generally, as the lay public has contributed money, physicians and surgeons have *pari passu* given freely their time and their skill during the best years of their lives to the same worthy object. The medical profession, therefore, no less than the public, will consider with interest the provisions of the Bill which has for its

object to incorporate the president and council of King Edward's Hospital Fund for London, and to provide for the management of the Fund, as well as the draft charter of incorporation under which the Metropolitan Hospital Sunday Fund seeks to define and to render permanent its constitution. Such steps concern others besides those who are immediately occupied in directing them. They are of more importance than any of the preceding acts of the institutions concerned and are subject to criticism from a different point of view. The organised collection and distribution of money in charity, or for any other purpose, is a matter of interest principally during the period in which the money in question is collected and distributed, and during which the effect of these operations is felt. Criticism may be withheld, or, being put forward, it may be either considered or disregarded, for an error made in one year can always be corrected in the next. When, however, Parliament is asked to pass a Bill, or when the Royal assent is asked to a charter, it is a case of legislating for posterity and in dealing with that which will affect posterity for good or ill too much foresight and too careful scrutiny of probable or possible developments can hardly be employed.

The Bill for the incorporation of King Edward's Hospital Fund is redolent of that high respect for the Throne and for the wise and enlightened monarch who occupies it, which all his subjects feel, and indeed share with the world, but we doubt whether that respect might not have been evinced without casting upon the occupant of the British throne for all time responsibilities which must inevitably weigh heavily and which may in conceivable circumstances prove irksome and difficult to sustain without liability to error. The Bill provides that His Royal Highness the PRINCE OF WALES shall continue his position of President of the Fund as President of the corporation "during the pleasure of the Sovereign" and that "every succeeding president shall be appointed by and hold office during the pleasure of the Sovereign." The whole of the management of the corporation is then vested in the President or through him in the Sovereign. The President appoints a council of such and so many as he may choose, and is to have absolute control of the property and funds of the corporation. Its management is provided for in these terms, to quote Section 5 of the Bill:—

"The direction control and management of the affairs and property of the corporation and the application of all moneys property and income of the corporation shall be vested in the President whose powers shall include the following—that is to say (a) power to appoint and at pleasure remove the members of the general council and of any other councils and committees hereinafter mentioned and trustees and treasurers secretaries auditors and other officers and to award them or any of them salaries or remuneration (b) power to appoint and dissolve councils and committees other than the general council and from time to time to delegate to any council or committee all or any of his powers of direction control or management as he may think fit (c) power to make vary and rescind bye laws rules and regulations for the management and administration of the affairs and property of the corporation and the procedure relating thereto including the use of the corporate seal and the keeping of regular books and accounts (d) power to direct the mode of collection of moneys for the corporation and the distribution and allocation of such moneys and of all property and income of the corporation to or for the benefit of all or such one or more

to the exclusion of the others of the hospitals of London as he in his uncontrolled discretion shall think fit and generally to determine the manner in which such moneys property and income shall be dealt with and applied for the purposes of this Act and in furtherance of the objects of the corporation (c) power to determine whether any institution proposed to be benefited is or is not within the limits of the objects of the corporation as defined by this Act and (f) power generally to do or direct to be done all acts and things which in his discretion he may deem conducive to promoting and effecting the objects of the corporation."

We need not labour our point with regard to the autocracy which is thus proposed to be instituted, but without disrespect to King EDWARD VII. or to his successors who may occupy the throne, we may point out that our present Sovereign succeeded as a man of mature judgment, with wide and cultivated sympathies, and with a knowledge of men and things which would have won for him high distinction in whatever position fate had placed him. Even if his successors may rightly be expected to emulate his example it is proposed to provide them with no assistance independent of their own unfettered judgment in the Bill from which we have quoted. This, we think, is wrong, and it should be possible to construct a definite constitution for the proposed corporation which should at one and the same time recognise to the full the grand services of our present King and his Heir Apparent and spare them the enormous responsibilities of unfettered discretion in the management of a Fund the expenditure of which must always be regulated by numerous technical influences.

With regard to the charter proposed to be granted to the Metropolitan Hospital Sunday Fund none can suggest that THE LANCET has from its inception been other than a staunch advocate of the objects of the Fund, devoting all the influence that it has had at its command to aiding the Fund in its annual collection and to making more widely known the beneficent work which it has carried out. And in the circumstances none can blame us if we quote with approval from the memorandum addressed to the President of the Privy Council by the Council of the Metropolitan Counties Branch of the British Medical Association the following paragraph:—"That the constitution of the Metropolitan Hospital Sunday Fund fails to provide for any representation in its Council and in its Committee of Distribution of medical practitioners who could best guide it in dealing with the medical requirements of hospitals, and that the public interest thereby suffers." The reasons for this remonstrance are briefly but effectively set out in the document referred to which was published in a recent issue of the *British Medical Journal*.¹ The memorandum dwells in detail upon all the reasons for believing that certain of the institutions annually subsidised by the Metropolitan Hospital Sunday Fund are conducted in a manner directly inimical to medical practitioners and alludes to many matters of grave interest in connexion with hospital management and with the expenditure of hospital funds upon the importance of which we have often dwelt in our columns. As we have pointed out, the contribution of the medical profession to the efficiency of the hospitals and to the carrying out of their work is to be reckoned side by side with, and in combination with, that of the ever-generous public, and it is by

the coöperation of the public and of the medical profession only that the hospitals of London can be maintained in the future as in the past as examples to the world of well-ordered public charity.

The Teaching of Public Health in Medical Schools.

THE demands made upon the time and energies of the medical student increase not only from generation to generation but even from term to term, and if the medical practitioner is to hold his own in connexion with the subject of public health it is, we fear, inevitable that he should devote more time to the study of that branch of medicine than is the case at the present moment. The progress of epidemiology during the last quarter of a century has been very notable and yet the medical schools are in some cases devoting no more time to its study than formerly. In several of the London schools some twelve lectures are set apart annually to a subject which could not be at all adequately dealt with in double that number. Some of the school committees take, we are afraid, but a lukewarm interest in the matter and they do not by their support of the lectures in public health indicate to the student that preventive medicine is a subject of first-class importance. Hence, the students are prone to regard the lectures in a somewhat perfunctory light and to attend the minimum number, unless perchance, as is sometimes the case, the lecturer by the interest and information which he is able to impart to his subject succeeds in holding his class together by the force of his own individuality.

No doubt greater use might be made even of this too brief course were there more coöperation and coördination between the lecturers at each school and a clearer understanding as to which aspect of infectious diseases, immunity, and so on, is to be dealt with by each lecturer. As it is, there are probably considerable repetition and overlapping. In so far as the lectures to students are concerned the school committee should endeavour to secure the services of a lecturer who has made a study of the science of preventive medicine rather than of administration and law. The student whose ultimate intention is to embrace general practice has no need or use for the special administrative wisdom of the medical officer of health or a knowledge of the statutes relating to common lodging-houses or the disposal of refuse. It is, however, essential that he shall appreciate fully the means by which disease is spread, the relation of the diseases of animals to those of man, the value of foodstuffs, and the methods of ascertaining the causation of disease in individuals and groups. He must be versed in his duties as a medical practitioner to the State. That, therefore, the lectures should be of greatest use to the student they should be delivered, as is not always the case, when he is in the most receptive condition and when he has already learnt something of bacteriology, medicine, and pathology. Such lectures should also lay a firm foundation for a later superstructure of public health knowledge should the student subsequently elect to proceed to the diploma in public health and to devote his life to this branch of work. But we are anxious to insist upon the fact that these lectures to medical students should make no pretence to prepare candidates for the diploma of

¹ Supplement to the Brit. Med. Jour., Oct. 13th, 1906.

public health and we should be glad to see the misconception which sometimes obtains upon this point rectified. For this diploma, which should be regarded as an honours certificate, much additional and detailed study is necessary in order, in the words of the General Medical Council, "to insure the possession of a distinctly high proficiency, scientific and practical, in all the branches of study which concern the public health." Preparation for this diploma may, of course, be undertaken by the lecturer on public health, who may also be in a position to give the candidates for such diploma the experience in practical work which is prescribed as part of the necessary curriculum. But there is no question that there is at times great difficulty in procuring the services of a local medical officer of health who as a whole-time officer can, consistently with his duties to his sanitary authority and to the public, devote the necessary time to the preparation of the candidate and to delivering lectures of a sufficiently high order. Hence it sometimes comes about that in the practical work the students are left rather too much to the sanitary inspector and consequently the candidates do not derive the full advantage from their association with the medical officer of health. Moreover, a thoroughly good epidemiologist and lecturer may be an imperfect administrator and *vice versa*.

It is therefore not always desirable to bestow a vacant lectureship upon a neighbouring medical officer of health and it may sometimes be found advantageous, both for the prestige of the school and the welfare of the students, to appoint as a lecturer an epidemiologist of a high order and as a demonstrator a medical officer of health having access to a suitable district or districts; and we should like to emphasise the desirability of affording to the candidates for the diploma in public health some experience of rural as well as urban administration. The methods and standards adopted in rural districts must of necessity differ somewhat from those found practicable in urban districts and an experience of both is likely to widen the mental horizon of the future medical officer of health and to help the development of his sense of proportion. With this end in view there might be advantage in appointing as demonstrator in the practical work some county medical officer who would have access to districts of different sizes and type—that is to say, if a county medical officer with a county where there was much work to be done would care to be troubled with the candidates. It has, of course, to be borne in mind that many medical officers of health who have districts involving constant attention and who take a pride in their administration do not care to be bothered with the supervision of candidates for the diploma in public health. Moreover, the remuneration offered is such as to fail to attract the best men to apply for the post of either lecturer or demonstrator, and if such men apply they do so from other motives than immediate material recompense. It is, however, essential that the school committees should satisfy themselves that whoever undertakes the practical work is in a position to show the students sanitary administration actually in operation, and that the student should be able to examine for himself the methods of keeping the books and how best to dispose of the inspectorial staff. He should also be able to visit all parts of the district or districts and be encouraged to follow up difficult cases in the law

courts. Probably the school committees are not all constituted in such a fashion as to enable them to select to the best advantage, and in these circumstances, perhaps always, they would do well to seek counsel elsewhere. It has indeed been suggested to us that as the preparation of future medical officers of health concerns the State both lecturers and demonstrators should be appointed by, or at least with the approval of, the State and there may be much to be said for this position. It might also be desirable that the General Medical Council or the Local Government Board should occasionally inspect the practical work of the candidates for the various diplomas in public health. But in the meantime we trust that the school committees may be able to allocate both more time and some fees to the teaching of this ever-expanding subject of preventive medicine.

The Workmen's Compensation Act, 1906.

No Act of Parliament designed for the benefit of the working classes has been of direct interest to so large a portion of the community as the new Workmen's Compensation Act which will come into force on July 1st and which, "except so far as it relates to references to medical referees and proceedings consequential thereon," does not apply to accidents taking place before that date. An abstract of the new statute, and particularly of the sections of interest to the medical profession, was given in THE LANCET of Jan. 12th, p. 112, and in this article Mr. ALBERT BENTHALL, whose previous contributions to the subject in our pages will be remembered by our readers, called attention to many of the innovations introduced. The duties which the new Act imposes upon the medical profession directly are for the consideration of those who may desire to become medical referees or who may fill the posts of certifying surgeons under the Factory and Workshop Act, 1901, and these will have to wait for full information until the Home Secretary and the Treasury have issued regulations with regard to them. But the medical profession at large is interested in any new law which renders the personal injuries inflicted by accidents the subject of inquiry with a view to the assessment of pecuniary compensation, and all members of the community employing domestic servants as well as all domestic servants themselves are now subjected to new liabilities or endowed with rights not hitherto enjoyed.

To quote from the definition given in the Act "workman" does not include any person employed otherwise than by way of manual labour whose remuneration exceeds £250 a year or a person whose employment is of a casual nature and who is employed otherwise than for the purposes of the employer's trade or business, or a member of a police force or an out-worker, or a member of the employer's family dwelling in his house, but, save as aforesaid, means any person who has entered into or works under a contract of service or apprenticeship with an employer, whether by way of manual labour, clerical work, or otherwise, and whether the contract is expressed or implied, is oral or in writing." The Workmen's Compensation Acts, 1897 and 1900, repealed by the new statute, were very short, but in spite of their brevity and their apparent

simplicity have given rise to an enormous amount of litigation. So far as this may have been the consequence of such brevity, the framers of the Act of 1907 have made up their minds to avoid it, for the new measure is not a short one when its ten sections and its three schedules, occupying 28 pages in all, are considered, and if the seeming simplicity of the statute of ten years ago was intended to give the impression that it was to be understood at a glance by the workman, no such idea has inspired those who drafted the present one. Presumably it has been found that any point worth disputing always and necessarily has been fought out by insurance companies on the one side and by workmen's associations on the other, and it has been thought that, as this must continue in any case, a statute which aimed at being explicit would serve its end best, although its full comprehension by laymen might present some difficulty. No doubt a large number of those most concerned will spend 4d. in purchasing the official text, and it will not be long before members of the bar who have made workmen's compensation their specialty will have volumes ready containing notes and explanations dealing with its various sections. Those who study the general provisions will find, among other points, that the "first fortnight" of incapacity for which a workman has hitherto not been able to claim has been altered so that he may not ask compensation for an accident which does not disable him from earning full wages for at least a week, and that where incapacity is for less than a fortnight the first week is not to be reckoned in computing the amount. These are provisions primarily of interest to the workman but likely to give no little trouble to the medical profession. It has been noted by Mr. BENTHALL that "If it is proved that the injury to a workman is attributable to the serious and wilful misconduct of that workman any compensation claimed in respect of that injury shall, unless the injury results in death or serious and permanent disablement, be disallowed." Curiously enough, one of the most recent cases in which compensation was withheld by the court of appeal on the ground of the workman's "serious and wilful misconduct" was one in which death had taken place, so that the man's personal representatives, who now have to go without their money, would have obtained it without any such question being raised had the accident taken place after July 1st. In the case referred to the workman had obstinately refused to make use of the guard provided for a saw driven by machinery, and the accident which actually killed him might have inflicted equal injury upon his fellows. It would, perhaps, have been useful if the new Act had given some definition of "serious and wilful misconduct," as well as of other expressions of a somewhat vague nature which it employs, so as to prevent, so far as possible, the necessity of recourse to the Court of Appeal for their interpretation. The *Lancet*, no doubt rightly, pointed out that in the case referred to, although the disobedience of the workman might constitute serious and wilful misconduct on his part, the fact that he appreciated the serious nature of his own behaviour was negatived by his conduct in persisting in it. Many will think that if the absence of such appreciation is to be put forward in argument in favour of a workman who, in spite of his employer's orders, endangers

himself and others, the sooner the law makes it plain that such disobedience may be serious and wilful misconduct the better, on the ground that the interests of workmen in general demand that all possible discouragement should be given to foolish recklessness.

The general tendency of the new Act, where it relates to medical referees, is to increase the importance of that post and to render it absolutely necessary that it should be filled by those enjoying the confidence of the medical profession around them. Instances of new powers given are to be found in a provision to enable a county court judge to summon a medical referee to sit with him as an assessor, and in Section 8, Subsection f, which gives a right of final appeal to a medical referee in cases where an employer or workman is aggrieved by the action of a certifying surgeon under the Factory and Workshop Act. This section, which may be described as the principal one of interest to certifying surgeons, provides that certain diseases defined in the third schedule shall rank as accidents, but protects the employer by provisions designed to prevent him from being rendered liable where the disease has been contracted under other employers than himself, and defines the duties and powers of the certifying surgeon in respect of the measures to be taken with this object and in connexion with these diseases. They are anthrax, poisoning by lead, mercury, or phosphorus and their sequelæ, and ankylostomiasis. We have said enough to show that the statute which in a few months time will become operative is of importance to the medical profession and to a wide public, many of whom will only become familiar with its details and with its effects by degrees. Even without the study of its text in detail, which has been recommended above, we can see that the new Act will afford ample scope for litigation in which difficult questions of fact and of law are likely to be involved, and that it will necessitate insurance by the employer and the forming of fresh combinations of the employed to meet its requirements. To medical men, who sometimes find the full meaning of Acts of Parliament difficult to appreciate, it may be desirable to point out that, like its predecessors, the new law does not provide for the payment of medical men called in in cases of accident (except where a workman killed by an accident has left no dependants) or for damages in which the expenses of medical attendance and of nursing are taken into consideration, but only for compensation based upon the average earnings of the workman before his accident computed according to rules laid down in Schedule I. of the Act. It may also be noted in like manner that no legislative innovation has been introduced to render compulsory surgical interference with a view to reducing the employer's liability by lessening the period of the workman's incapacity, a very difficult matter to deal with satisfactorily, but with regard to which discussion has at times arisen.

DONATIONS AND BEQUESTS.—The honorary secretaries of King Edward's Hospital Fund for London have received £20,179 from the executors of the late Mr. Alfred Belt.—The late Mr. G. Phelps of Bristol has bequeathed £500 to the Royal Infirmary, General Hospital, and Children's Hospital.

Annotations.

"No guld nimis."

THE MEDICAL DIRECTORY FOR 1907.

THE issue of this work for 1907, so indispensable to the medical profession, appeared during the closing weeks of 1906. Comparing the edition for the current year with that for the year just passed, we find that the total number of names is 39,365, an increase of 444 over the total 38,921 in 1906. Taking the several regions into which the Directory is divided, we find that the number of names in the London list for 1907 is 6512, as against 6438 in 1906. The provincial list for England for 1907 contains 17,080 names, as against 16,976 in 1906. Wales for 1907 has 1232 names, as against 1217 names in 1906. Scotland for 1907 has 3815 names, as against 3785 in 1906. Ireland for 1907 has 2672 names, as against 2654 in 1906. Registered practitioners abroad number 4822 in 1907, as against 4666 in 1906. The medical services—naval, military, and Indian—number 3223 for 1907, as against 3165 for 1906. There is thus, it will be seen, an increase in every department of the profession which is dealt with in the Directory. The "Too Late" list for 1907 contains nine names, for 1906 20 names. The introductory article on the principal laws affecting the medical profession is as full of information and as useful as ever and the book is printed and edited with that care which the publishers, Messrs. J. and A. Churchill, have taught us to expect from them.

WEATHER IN WAR TIME.

AT a recent meeting of the Royal Meteorological Society the president, Mr. Richard Bentley, delivered an address upon the above subject. He showed how upon upwards of 300 occasions the course of history was greatly influenced by weather conditions. Often invasions were frustrated or greatly impeded, from the time of the destruction of Mardonius's fleet off Mount Athos to the attempted French invasion of Ireland. Fogs also played an important part in history. Lord Anson in a single ship loaded with Spanish treasure slipped unperceived through the entire French fleet and the great Duke of Marlborough contrived to get his army across the Scheldt in the teeth of the enemy in a river mist. Reference was made to the difficulties overcome in crossing the snow on the Alps by Hannibal, Napoleon, Massena, Souvaroff, and Macdonald, and also to the march of Colonel Kelly's Sikhs to the relief of Chitral. Mention was also made of the hailstorm which smote Richard I.'s men at Ascalon, of the sleetstorms at the battles of Hohenlinden and Eylau, and of the wild weather during the memorable retreat from Moscow. The important part played by ice was shown by the Swedish army on one occasion invading Denmark across the frozen Baltic and by the Russians in 1809 similarly crossing over the frozen sea to Sweden; also by the ice inclines in the passes prepared to hinder the Hungarians from crossing the Balkans and the great ice forts built by the Austrians in the Tyrol which could neither be clambered up nor shattered and were proof against all the French attacks. Many other instances were given, but we may mention two which are at any rate not referred to in the official abstract before us and are sufficiently remarkable to deserve special notice. The one is the defeat of the barbarians by M. Aurelius, A.D. 176, owing to a sudden hailstorm which, according to ecclesiastical history, came on at the prayer of the Melitene Legion, afterwards known as the Legio Fulminatrix, and the other the sudden frost and gale which upset the plans of Maurice for the combined attack by water and land upon Antwerp in 1622,

then in the hands of the Spaniards. From a medical point of view weather has many times affected the course of campaigns by being favourable to the spread of epidemics such as typhus and typhoid fevers and more especially when the campaign included a long siege. Abnormally wet or dry seasons have also brought about their respective effects upon armies. Extreme heat and drought, leading to heat exhaustion and parching thirst, were in great measure responsible for the terrible disaster to the arms of Portugal at Alcacervir in 1578.

THE STRENGTH OF SURGICAL SUTURES.

M. A. Astruc has published in the *Journal de Pharmacie et de Chimie* of Nov. 16th, 1906, an interesting article on the determination of the strength and other physical characters of catgut, silk, and other surgical sutures. The strength of catgut and other materials is usually determined by ascertaining how much weight is required to break the stretched fibre, but M. Astruc points out that sutures as employed by surgeons are not submitted simply to direct tension, the knots having to be taken into account. The breaking strain is not the same in the case of a simple thread as it is when a knot is present. Hence M. Astruc has determined the breaking strain for both simple and knotted sutures. It is interesting to note that the figures given demonstrate the slight superiority of a surgeon's knot over simple knots. The following table gives a few of these figures:—

Breaking Strain (in kilogrammes).

Size of sutures.	Simple suture.	Suture containing a surgeon's knot.	Suture containing a simple knot.
<i>Catgut.</i>			
000	3.0	2.7	2.4
1	7.3	5.5	5.0
5	11.6	7.7	7.1
10	33.0	17.5	16.5
<i>Silk.</i>			
000	3.0	2.2	2.0
1	4.9	3.5	3.4
5	10.4	9.4	9.3
10	18.7	17.1	17.0

These figures justify the conclusion that the force required to break a suture provided with a knot represents only a fraction of that required to break a suture which is simply stretched. This is particularly seen in the case of the thicker threads of catgut; thus a No. 10 catgut suture breaks under a strain of 33 kilogrammes when simply stretched, whereas the presence of a surgeon's knot causes it to break under a strain of 17.5 kilogrammes. But in the case of silk the presence of a knot only produces a relatively slight weakness in the threads.

MEDICAL CANDIDATES FOR THE LONDON COUNTY COUNCIL.

EVER since the London County Council came into existence it has numbered medical men among its members. Their presence, indeed, has been urgently necessary in view of the work which the Council has to do. It supervises the administration of the Public Health (London) Act, 1891. It also administers within the County of London the Infant Life Protection Act, the Inebriates Act, and the Contagious Diseases (Animals) Acts, manages six large lunatic asylums, appoints coroners, is responsible for the main drainage of the metropolis, and controls the education, mental and physical, of London's children. In all this work the advice of medical councillors

must often prove extremely valuable and sometimes indispensable. Even in such matters as the maintenance of the parks and the provision of means of recreation and locomotion important medical questions must frequently arise. Sir William J. Collins, M.P., is now retiring from the London County Council after many years' service, but three other members of the medical profession are announced as likely to seek re-election on March 2nd. These are the deputy-chairman of the Council (Dr. E. B. Forman) who will stand for South Kensington, Dr. A. Salter (Bermondsey), and Dr. R. M. Beaton (North St. Pancras). In addition, Dr. W. Lansdale is a candidate for West Newington, Professor W. R. Smith for St. George's-in-the-East, Dr. John Davies for Hoxton, and Mr. Percy Vesper for West St. Pancras. The candidates also include a non-medical councillor well known to many members of the profession in the person of Mr. R. A. Robinson, who has recently resigned the presidency of the Pharmaceutical Society of Great Britain in order to devote more time to the leadership of the "Municipal Reform" party at the coming election of the London County Council.

THE ADVANTAGES OF INVESTIGATING THE UNLIKELY.

IN the *Journal of the Society of Chemical Industry* of Dec. 31st, 1906, there appears a report of a discourse by Sir William Ramsay on the Advantages of Investigating the Unlikely. He drew attention to the unsuitableness of the old legal saw, "*De minimis non curat lex*," as a motto for a man of science. On the contrary, science and industry must attend to trifles. It is possible, he supposed, in real life to judge what are trifles and what are not, but in science it is not always easy to draw the distinction. A man who studies the markings on a butterfly's wing or counts the bristles on the antennæ of a bee may not appear to a chemist to be doing anything important, but such markings may have led a Darwin or a Wallace to propound the theory of natural selection and the bristles may be the organs of a sense unknown to us by means of which the bee gains impressions from some form of radiant energy incapable of impressing our grosser or differing sense-organs. It would thus seem that there are no negligibles in nature. Sir William Ramsay referred to Faraday's observation that a current flowed when a magnet was withdrawn from a coil of wire. This simple experiment led the way to the enormous electrical developments of modern times, including countless dynamos transmitting the energy which furnishes us with light and power, and which may some day be utilised for distributing heat over our cities. After illustrating his theme by reference to his own work on the gases of the atmosphere Sir William Ramsay drew attention to the advantages of attempting such investigations. First of all, it satisfies the curiosity which members of the human race possess to enlarge their knowledge. Next, it correlates knowledge and by supplying missing links it increases the value of what is already known. Lastly, it shows that more is sometimes achieved by speculative science—trying for results against long odds—than in slowly and laboriously accumulating results which could have been foretold. Sir William Ramsay's remarks apply with force to the study of medical problems. The man of science should, above all, learn to approach a problem with an open mind; a pre-conceived opinion may be fatal to the elucidation of the truth. The mere mental act of deciding whether or not a problem affords a promising subject for investigation is a form of preconceived opinion and as such should be avoided. The correct attitude to adopt is doubtless that of the man who perceives where there are gaps in human knowledge and devotes his energies to filling in those gaps. The early experiments of Pasteur might not to many investigators appear to offer important results but they led to the

opening out of the new science of bacteriology, one of the most important developments of which was the discovery of the antiseptic system of surgery.

THE MEDICINAL ACTION OF ARISTOLOCHIA CYMBIFERA.

A PRIX Martin-Damourette has been awarded to M. Lucien Butte for his researches on the physiological and therapeutic action of *aristolochia cymbifera*, an account of which is given in the *Comptes Rendus* of Dec. 17th, 1906. The plant is highly esteemed under the name "guacho" by the people of Mexico as a sovereign remedy in cases of snake-bite. M. Butte has shown that it possesses no value in this respect, though it has other valuable properties due to the presence of an active resinous substance, guachol. It is a powerful analgesic; it also exerts a retarding influence upon nutrition and lowers the temperature. On this account guachol is recommended by M. Butte as a therapeutic agent in many painful affections of neuralgic origin.

SUNSHINE DURING 1906.

ALL the following figures, with the single exception of those for Shanklin, have been compiled from the reports published either weekly or monthly by the Meteorological Office and are therefore trustworthy. As the results are all obtained (except at Shanklin) by the Stokes-Campbell burning recorder they are strictly comparable. The notable excess of hours at Shanklin is probably, but not necessarily, due to the use of a different kind of recording instrument—the Jordan photographic recorder, which is sometimes more

Sunshine during 1906.

* No trustworthy average.

sensitive. It was generally recognised that last year was more than usually bright and the figures amply bear out the popular opinion. Not only was the sunshine much in excess of the average, but except at some places in the north-west it was also greatly in excess of that of 1905, which,

again, was a bright year except on certain parts of the south and south-west coasts. It is very satisfactory to find that the greatest excess on the average is in London (Westminster), where the aggregate number of hours, 1513, represents an excess of more than an hour per day. The metropolis was also brighter than Nottingham, very much more sunny than either Manchester or Glasgow, and nearly as bright as Dublin. The most sunny resorts were Shanklin, Torquay, and Jersey, where the aggregate number of hours was nearly double that recorded at the duller places—Glasgow and Manchester. But there was very little difference between the resorts on the east, south-east, and south coasts regarded generally, the only places having less than 1900 hours being Margate and Brighton. During 1905 the most sunny spot in the kingdom was Lowestoft and again last year it was very high on the list. In the north-west the sunshine was more prevalent at Rhyl, Llandudno, Douglas, Isle of Man, and Blackpool than elsewhere, but all these had about an hour per day less than the south and south-east of England. The two inland Welsh resorts in Wales given in the table were much more cloudy than Bath and Tunbridge Wells, and were even less sunny than London. Considering its distance from the coast Tunbridge Wells was exceptionally bright, its total number of hours, 1953, being only a trifle less than that at Bourne-mouth. The only place representing the east of Scotland, Aberdeen, enjoyed but little less sunshine than Scarborough, and more than London and many parts of the English midlands.

SPONTANEOUS AMPUTATION OF AN APPENDIX VERMIFORMIS IN THE SAC OF A FEMORAL HERNIA.

IN the *Albany Medical Annals* for January Dr. F. G. Schaible has reported a case of a very peculiar condition—spontaneous amputation of the vermiform appendix in the sac of a femoral hernia. Since the radical cure for hernia has become customary a large number of cases has been recorded in which the appendix, alone or accompanied by omentum or intestine, occupied a hernial sac. In the majority the sac has been a right inguinal one. Pathological conditions of the herniated appendix are not uncommon. According to Jopson the tendency to inflammation is greater than in the non-herniated appendix. In many cases symptoms supposed to be due to an inflamed or gangrenous strangulated hernia were due to an inflamed or gangrenous appendix which had become adherent to a hernial sac. But no case of spontaneous amputation of the herniated appendix such as the following appears to have been recorded. A woman, aged 80 years, was admitted into hospital. She first noticed a small lump in the right groin about eight years before. This gradually increased to the size of a goose's egg and was recognised as a hernia. At first it produced no symptoms, but later, on the entrance of a portion of intestine into the sac, there were a feeling of weight and extreme pain. At such times she was able to reduce the hernia and was then relieved. She had worn a truss for three years. The hernia came down about every six or eight months. Before admission the patient was seized with slight pain in the right groin which increased until it became intolerable. She did not vomit; the bowels were constipated and the hernia was irreducible. There was a sausage-shaped tumour in the right groin which measured 8.5 by 3.5 centimetres. On opening the sac it was found to contain from three to four inches of ileum, very congested and almost black. The neck of the sac was very tight, being of the size of a finger, and it was necessary to incise the constricting band somewhat. Some hot saline solution was poured on the gut and the colour began to return with contraction of muscular fibres. After

considerable efforts the gut slipped back into the abdomen. A body which was considered to be a peritoneal lipoma was attached to the inner surface of the sac. On further examination it appeared to be a rather short obliterated appendix with smooth ends and without caecal attachment. It seemed to have been amputated by pressure and a definite mesentery was attached to it. A tongue of omentum was removed with the sac. Uninterrupted recovery followed. Examination of the specimen showed attached to the sac a mass of adipose tissue resembling a meso-appendix. Attached to the latter and slightly imbedded in it was a cord-like structure which measured four centimetres in length and half a centimetre in diameter. Its surface was smooth, glistening, and pink-grey and it was rounded at both ends. To these ends were attached by fibrous bands small masses of adipose tissue. Adherent to the hernial sac at its under surface by a long fibrous band was a piece of omentum. Microscopic examination of the appendix showed that the lumen was obliterated and the mucosa completely replaced by fat and connective tissue containing a few lymphoid cells. The musculature was slightly atrophied and there was a slight infiltration of lymphocytes and eosinophiles. The peritoneal coat showed many small hæmorrhages. That the structure was appendix and not some other obliterated tubular structure or ligamentous mass was definitely shown by the character and arrangement of its outer coats. Dr. Schaible thinks that the obliteration of the appendix took place before it entered the sac and that the amputation was due to gradual constriction of the proximal portion of the appendix between the divisions of the fascia lata forming the boundaries of the femoral ring, aided perhaps by the pressure of the truss.

THE MULTUM IN PARVO MEAL.

IT is a notion fondly cherished by some people that the day will come when the human race will subsist entirely on highly concentrated food. The time occupied in eating the daily meals will be saved by swallowing a tablet of concentrated essence and all questions of fastidiousness for food will be banished while the dyspepsia arising from an over-bulky and hastily swallowed meal will finally disappear. The idea is, of course, utterly fallacious and plainly opposed to sound physiological teaching. Such a dietetic consummation thus innocently entertained would probably end in the extinction of the race by disease as a sequence of inanition. The fact is that the volume of food serves a definite purpose in the body. Highly concentrated foods are prone to be very irritating to the digestive organs and they also tend to exhaust the secretory powers of the stomach, the digestive juices being poured out in a quantity far in excess of the requirements of that food and thus secretory energy, which is the key to assimilation, is uselessly spent. Concentrated meat essences containing merely the extractives of meat are, for example, the most powerful exciters of gastric secretion that we possess but when partaken of exclusively they avail nothing in the direction of real nutrition and lead most likely to serious waste of tissue; in a word, to starvation. They serve admirably, however, as a kind of condiment or adjuvant to food, preparing the ground for its reception and digestion. Hence soup is the first item in the physiologically well designed meal. When kept within reasonable limits the bulkiness of food excites a healthy stimulus to the muscular action of the stomach and the bowels, and altogether the indications are plain that the digestive organs are not adapted for dealing with highly concentrated food. Food must have, so to speak, a physiological ballast before it is acceptable to the digestive processes. The simplest way of reducing the bulk of most foods is by depriving them of their natural

moisture. Eight pounds of mutton or beef would thus be reduced to two pounds of dry substance but the water must be replaced to a large extent before the meat can be cooked or eaten. There are, of course, particular cases, as, for example, in illness, in which it is necessary that the diet should be sparing in quantity and yet highly nutritious in quality but in health the use of concentrated foods is physiologically absurd, if not mischievous. The time when men will take for their meals, and be satisfied with, as much concentrated food as will cover a threepenny-piece can never be, so long as the human mechanism is as it is and physiological laws are inexorable.

INVALID TRAVEL IN SOUTHERN EUROPE.

"WHEN will the Italian Government, in the management of its railways, put in practice the police regulations so justly demanded by the outside world for the safety of passengers?" This (writes an Italian correspondent under date Jan. 19th) is the question put by the *Gazzetta del Popolo* of Turin to its exceptionally numerous and influential *clientèle* at the close of an article on the recent murderous assault on an English lady on the much-frequented line between Turin and Modena. When, indeed? For the last six months the inconveniences (to put it mildly) that have followed the transfer of the Italian railways from private companies to the State have been bad enough to deter not a few of the travelling public from using them—one of the latest, and not least unpleasant, of these "inconveniences" being the deadly cold complained of by first- and second-class passengers from the want of adequate heating apparatus. The other day, between Milan and Rome, the inmates of a first-class carriage had to endure the bitter cold of an unheated train as far as Piacenza where at last footwarmers of a primitive type were provided as the *calorifères* were found to be quite out of gear. Serious enough in the case of invalids coming in quest of warmth to the "Sunny South," this "inconvenience" is but trifling compared with the loss of life and injury to limb incurred on the same network, where there have been accidents enough, more or less fatal, to warrant the Milanese *Secolo* in introducing its report of them under the headline "Una Giornata di Scontri" (a day of collisions). And now, as if unpunctuality, discomfort, and general "inconvenience" were too little of a deterrent, the recent "scontri" have been enhanced by something far worse than the all too notorious luggage robberies—namely, a dastardly assault by which an English lady, esteemed for her proficiency and devotion as a nurse in the Boer war, is now lying in a critical state at the Chambery Hospital. Providentially, the promptitude and skill with which surgical intervention came to her relief make her recovery so far hopeful that she has been able to describe her assailant so clearly as to put the police on his track and to justify the newspapers in announcing his arrest as imminent. Coincidentally with the chorus of indignant protest which the Italian press of all political shades is addressing to the Government for immediate and effective reform in its railway management we read in the same journals of meetings of the Association for Promoting the Influx of Foreigners, meetings at which, among the "attractions" and "lures" held out to the English-speaking world, the improvement of the railway service (to say nothing of better hotel accommodation and a less persistent resort to tinned meats and vegetables in the cuisine) is hardly ever mentioned. The association in question is a wealthy as well as an influential body; on its committee senators and members of the Chamber of Deputies are conspicuous for their social weight and public spirit and the names of some of the leading hotel proprietors and merchants are also *in evidence*. Let it bring its undoubted authority and

influence to bear on the Government, in Parliament and through the press; let the administration feel its pressure at elections, supplementary as well as general; let it, in short, act with the energy and force to be expected from an interest—that of the "foreign import" (as the travelling world is somewhat cynically termed)—from which Italy derives a third of her annual revenue, and then we may see the railway service and the "accommodation" it leads up to become what they ought to be—a ready, a comfortable, and an attractive means of bringing the unique resources of Italy as a health resort, combining mental recreation with physical enjoyment, within the reach of a far more numerous *clientèle* than she has ever hitherto had. As it is, access by railway, long somewhat of "a chastened joy," has, thanks to accidents, luggage robberies, and murderous assaults, become so much of a deterrent that the press is more than justified in demanding from the Government an answer to the old, old question: "Quousque tandem?"

ATMOSPHERIC NITRATE.

WE have informed our readers from time to time of the progress that has been made in regard to fixing the nitrogen of the air and converting it into nitrate for agricultural and industrial purposes. The announcement is now made that Professor Kowalski and Professor Mosciol of the University of Freiburg have succeeded in obtaining nitric acid from the air in a simple, direct, and economical way, thus realising the remarkable prediction made by Sir William Crookes as to the production of agricultural fertilisers from the air in his presidential address at the meeting of the British Association for the Advancement of Science at Bristol in 1898. It may be surmised that the new discovery relates to the economic production of nitrate from the combustion of nitrogen by means of an intense spark discharged through air, the electric energy being derived from water power. Further developments will be awaited with the keenest interest, since this announcement obviously bears on the great question of the world's food-supply. Cavendish little thought that his classic experiment in which he showed that nitrous fumes were formed on passing electric sparks through the air was going to have such immense importance in the practical affairs of the world. The country which possesses an illimitable field of natural power will, of course, outstrip all others which are compelled to rely on artificial power in the new manufacture, while it may be anticipated that the natural sources of nitrate, as, for example, those in Chili, will largely be abandoned except for relatively local application.

THE ROYAL SANITARY INSTITUTE.

THE usual course of lectures and demonstrations for sanitary officers will be given in connexion with the Royal Sanitary Institute, London, during the months from February to May. The lectures are held in the Parkes Museum, Margaret-street, London, W., at 7 P.M., generally on Mondays, Wednesdays, and Fridays, with a few exceptions, and the inspections and demonstrations take place generally on Mondays, Wednesdays, and Saturdays, on the first two mentioned days either at the Parkes Museum at 6 P.M. or elsewhere at 2 or 3 P.M., and on Saturdays elsewhere at about the last-named hours. The course is divided into two parts. Part I. comprises four lectures on elementary physics and chemistry in relation to water, soil, air, and ventilation, and meteorology; 21 lectures on Public Health Statutes, the practical duties of a sanitary inspector, municipal hygiene or hygiene of communities, and building construction in its sanitary relations and local physical conditions. The inspections and demonstrations in

-connexion with the lectures include visits to disinfecting stations, dairy premises, municipal dépôts, artisans' dwellings, offensive trades, waterworks, common lodging-houses, sanitary works in progress, and refuse and sewage disposal works. Part II. of the course consists of seven lectures on meat and food inspection, including taking samples of water, food, and drugs for analysis. Practical demonstrations of meat inspection are given. The fee for Part I. is £2 12s. 6d., for Part II. £1 1s., or for the complete course £3 3s. Members and associates of the institute are admitted to the lectures without payment but cannot introduce friends.

RADIUM IN OPHTHALMOLOGY.

A LAUDATORY article on the beneficial effects of radium emanations in various diseases of the eyes appears in the *Clinique Ophtalmologique* for December, 1906, from the pen of Dr. Thiebault of Algiers, who appears to have had considerable experience in the application of this remedy. The cases in which he has observed great improvement in the symptoms are in those of epithelioma, of episcleritis, both superficial, circumscribed or nodular (*doutonneuse*), or general, and of trachoma. He states that he obtained the complete removal of rodent facial epithelioma with a pre-auricular ganglion of eight months' duration and of seven millimetres in diameter by exposure of the ulcer to the radium emanations for 30 minutes at a time for eight weeks. In a case of superficial episcleritis complete recovery followed three applications for three or four minutes to each nodule. A case is recorded of diffuse scleritis of a serious character affecting both eyes and presenting a remote resemblance to leprosy, the cornea being thickened and opaque with large sinuous veins in some parts and a xerotic condition in others. Here repeated applications of radium gradually, so to speak, liquefied the xerosis in the course of four months and with several relapses, the sclerotic resumed its pearly aspect, the vessels resumed their ordinary size, the conjunctiva was easily made to glide on the sclerotic, and, though the cornea remained opaque to the observer, vision, which had been completely lost at the height of the attack, was so far recovered that the patient could dimly see fingers at the distance of a foot and could recognise bright colours. The case did not undergo further improvement by the administration of adrenalin. Considerable success has also attended the use of radium in cases of trachoma, of which he reports several. He thinks that in the future radium-therapy will be largely and successfully employed.

DEATH FROM AN ELECTRIC SHOCK WHILST HANDLING A TELEPHONE RECEIVER AND AN ELECTRIC LIGHT LAMP.

In the *Boston Medical and Surgical Journal* of Dec. 20th, 1906, Dr. A. E. Paine has reported the following extraordinary case which reveals a new danger from the modern development of the use of electricity for lighting and telephones. He was summoned to an oil works where the superintendent was stated to be dead. On arrival at the office he found that the employees had been too frightened and did not dare to touch the telephone. The superintendent was lying on his back with the telephone by his side. The cord of the receiver was broken and the latter lay on the floor. To the right of the body was a broken incandescent desk lamp which was suspended from the ceiling by a cord. The bookkeeper said that the superintendent had telephoned to his house that he would not come home for a little time, and had just hung up the receiver when a crash and a flash of light occurred. On going into the inner office the bookkeeper found the superintendent lying on the floor. He was not positive whether the telephone or the electric lamp cord was in the hand of the deceased, but on trying

to disengage it he received a shock which threw him against the wall. Examination of the body showed a burn on the inside of the thumb, a deep burn extending to the bone on the forefinger near the knuckle, and a deep burn in the palm extending nearly to the bone. The telephone cord, which was not properly insulated and consisted of wire covered by light webbing, was burned through. The nickel-plated handle for holding the receiver of the telephone was burnt on the inside. Dr. Paine thinks that when the deceased was putting on the receiver his hand came in contact with the metal handle, that at the same time he was holding the desk lamp in order to move it, and that he received the charge from the electric light supply. Instantly the plugs at the telephone exchange were blown out. At the inquest an electrical expert explained that this was due to the fact that the telephone wire was not powerful enough to stand the amount of electricity passed into it. There were 3500 volts on the principal wire and 1500 would be sufficient to kill. The telephone wires in the ordinary way simply carried electricity from batteries amounting to about four volts. It seems that at some point (the locality of which is not stated) the electric and telephone wires crossed and were swayed together by the wind. The insulation was there burned off and the whole 3500 volts passed into the telephone wire.

POOR-LAW REFORM COMMISSION (IRELAND).

IN THE LANCET of Nov. 24th, 1906, we commented in a leading article upon the report of the Viceregal Commission appointed by the then Lord Lieutenant of Ireland in 1903 to examine into the question of Irish Poor-law reform. We quoted a passage from the report pointing out that the establishment of a State medical service for Ireland would appear to involve the payment by the State of the whole instead of half of the salaries of medical officers as at present. An Irish correspondent now writes informing us that in reality the State pays three-quarters of the whole cost and not half. He bases his argument upon the following method of procedure and figures. When a board of guardians wishes to raise money for the purposes of Poor law expenses the board makes an estimate which is submitted to the Local Government Board and a demand note is sent to the county council which is also in communication with the Local Government Board. The Local Government Board then pays the county council such sums in relief of local taxation as the council may be entitled to. The county council then deducts the amount due to the guardians in respect of union charges from the amounts specified in the demand note and then strikes a rate to raise the balance required. The amount so raised, together with the amount paid by the Local Government Board in relief of local taxation, is then placed by the county council to the credit of the guardians who pay the medical officers. According to the Local Government (Ireland) Act of 1898 the income of the county council is derived from two sources (Section 51)—a levy in the form of a poor-rate and certain free grants in relief of local taxation. These free grants are: 1. A grant from the account for the reduction of local taxation, the funds of which are supplied by certain excise and other licence duties plus a grant of £79,000 per annum (Section 58). It is from this account that the Local Government Board pays the half of the medical officers' salaries and half the cost of medicines and certain educational expenses (Section 58). 2. A free grant from the agricultural grant (Section 48). Thus it works out that half the salary of medical officers is paid by the Local Government Board through the account for the reduction of local taxation. The remaining half of the salary is a charge on the poor-rate, but the poor-rate is annulled by a

further free grant from the agricultural grant, so that the county council really only has to pay about half the sum levied for poor-rate. Our correspondent further gives us the actual figures of an Irish union in a recent year, which are as follows. Demand note of the guardians, £4420. This was made up as follows :—

	£	s.	d.
(1) Per agricultural grant, Section 48	1363	10	0
(2) Half refund of educational and medical expenses (from Account for Reduction of Local Taxation), Section 53.	464	0	0
(3) Government grant other than agricultural, such as Probate and Estate Duties	472	0	0
Total grants	£2319	10	0
Amount raised by County Council by means of poor-rate	2109	10	0
	£4420	0	0

The total amount of grants in aid was thus £2319 10s., while the county council levied £2100 10s., the amount levied by the county council being thus £109 10s. less than half of the total amount, or in other words the State contributions amount to £219 more than the sum raised by the county council poor rate.

UNIVERSITY COLLEGE, LONDON.

A COURSE of eight lectures on Certain Fundamental Problems in Physiology common to Animals and Plants, to be given by Dr. W. M. Bayliss, F.R.S., on Wednesdays, at 5 P.M., began on Jan. 23rd. The phenomena to be dealt with will be taken as far as possible in the following order: Assimilation of Carbon, Enzyme Action, Mechanism of Oxidation, Properties of Colloids, Permeability of Membranes, and Transmission of Stimuli. These lectures are open to all students of the University of London, also to qualified medical men and to such other persons as are specially admitted.

THE EARTHQUAKE IN JAMAICA.

THE calamity which has overwhelmed the city of Kingston in Jamaica exhibits all the appalling incidents which are almost necessarily associated with an earthquake of any severity. There are the wholesale destruction of buildings, the hopeless feeling of insecurity, the almost universal outbreak of fire, and the sinking of a portion of the land into the sea. The medical aspects of the results of an earthquake in a densely inhabited region are, of course, serious. Apart from the grievous injuries inflicted by masses of falling buildings and the burns from the fire which always breaks out the more remote results have to be considered. Want of food and exposure, in addition to the lowering of the resisting powers of the body by mental anguish, lead to many deaths from pneumonia or other acute diseases, while the presence of numbers of unburied dead and the almost certain defilement of the water-supply may give rise later to severe epidemics. Sir James Crichton Browne, however, writing in the *Times* of Jan. 19th, points out that in one particular the disaster may prove a blessing in disguise by its having removed in a very thorough manner a number of grossly insanitary houses. The rebuilding of the city therefore offers an opportunity for greatly improving its general hygienic conditions. We may add that the general behaviour of the authorities seems to have been excellent and that everything possible is being done in collecting and burying the bodies of the dead, but with regard to the wounded and injured the medical resources of the island are apparently seriously strained. This being so we can only regret the unfortunate misunderstanding which appears to have arisen between the Governor and the admiral in command of the United States squadron which at first rendered admirable help. Among the numerous victims was Dr. Thomas Savage of Birmingham, of whose career we give details in another column. Valuable aid was also given by

Mr. Arthur Evans, M.R.C.S., L.R.O.P., the surgeon of the steamship *Port Kingston*, which was converted into a hospital by leave of Sir Alfred Jones.

A COMPLIMENTARY dinner is being organised to commemorate the bestowal by the King of the honour of C.M.G. on Mr. Pietro Michelli, the Secretary of the Seamen's Hospital Society, Greenwich. The committee consists of Sir Patrick Manson, Sir William Barnett, Sir Frederick Young, Mr. Percival A. Nairne, Professor R. T. Hewlett, and Mr. James Cantlie. The dinner will take place at the Trocadéro Restaurant, London, on Friday, Feb. 15th next. Mr. Nairne, the chairman of the Board of Governors of the Seaman's Hospital Society, will preside. We are authorised to state that anyone who has not been reached by circular and who would like to be present can obtain a dinner ticket at the price of one guinea on application to the honorary secretaries at the offices of the Seamen's Hospital Society, 13A, Cookspur-street, Charing Cross, London.

A TELEGRAM from the Governor of the Mauritius received at the Colonial Office on Jan. 18th states that for the week ending Jan. 17th there were 6 cases of bubonic plague and 4 deaths from the disease.

VITAL STATISTICS.

ANNUAL BIRTH-RATES AND DEATH-RATES FROM THE SEVEN CHIEF EPIDEMIC DISEASES IN ENGLAND AND WALES DURING 1906.

	Births.	Annual rates per 1000 living			Infant mortality— Annual death-rate of infants under one year per 1000 births.
		Deaths from all causes.	Deaths from seven chief epidemic diseases.		
England and Wales	27.0	15.4	1.73		133
76 great towns	27.9	16.0	2.24		146
142 smaller towns	26.5	14.4	1.70		133
England and Wales, less the 218 towns	25.3	15.0	1.18		115

Note.—These figures are provisional.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8747 births and 5549 deaths were registered during the week ending Jan. 19th. The annual rate of mortality, which had been equal to 22.4 and 20.7 in the two preceding weeks, further declined to 18.1 in the week under notice. During the first three weeks of the current quarter the death-rate in these towns averaged 20.4 per 1000, the rate during the same period in London being 21.4. The lowest death-rates in the 76 towns during last week were 8.7 in Handsworth, 9.0 in King's Norton, and 9.1 in West Bromwich and in Reading; the rates in the other towns ranged upwards to 25.8 in York, 26.0 in Hull, 27.6 in Rotherham, and 35.3 Middlesbrough. The 5549 deaths in the 76 towns showed a further decline of 799 from the high numbers returned in the two preceding weeks, and included 381 which were referred to the principal epidemic diseases, against 478 and 423 in the two previous weeks; of these, 133 resulted from measles, 92 from whooping-cough, 56 from diphtheria, 34 from scarlet fever, 33 from diarrhoea, 23 from "fever" (principally enteric), and not one from small-pox. The deaths from these epidemic diseases were equal to a mean annual rate of 1.2 per 1000 in the 76 towns; the rate in London from the same diseases did not exceed 1.1. No death from any of these epidemic diseases was registered last week in Bristol, Croydon, Gatehead, Hornsey, or in four other of the 76 towns; the annual death-rate

and the total number of cases of disease and injury was 81,563, which is in the ratio of 734.71 per 1000, being a decrease of 119.29 per 1000 as compared with the average ratio of the last eight years. The total number of persons invalided was 2653, which is in the ratio of 23.89 per 1000, and shows a decrease of 4.98 in comparison with the average of the last eight years. The ratio of invaliding for disease alone was 22.02, and for injury 1.87 per 1000. Of those stations where comparisons can be made with the figures for 1904, the Mediterranean and irregular force show increased invaliding ratios; China, East Indies, Australia, and Cape of Good Hope show diminished ratios. Deaths number 433, a ratio of 3.9 per 1000, showing a decrease of 1.42 per 1000 as compared with the ratio for the last eight years. Of these deaths 305 were from disease and 128 from injuries. The death-rate due to disease alone was 2.74, and that due to injuries was 1.15 per 1000. Compared with 1904, the stations showing an increased death-rate are the Mediterranean and the irregular force; the remainder of those for which comparisons are made show a decreased rate. The Channel Fleet shows the lowest sick-rate and the irregular force the highest. There are many interesting notes and figures to be found under the heading of General Diseases and in the brief reports of the various stations. The appendix contains Notes on the Distribution of Mediterranean Fever in the Fleet during 1905, Sc., by Fleet-Surgeon P. W. Bassett-Smith, R.N.; a Report of Work Done in the Laboratory at the Royal Naval Hospital, Malta, during the Year 1905 by Surgeon H. C. Whiteside, R.N.; a Statistical Report of Mediterranean Fever Cases occurring amongst the Nursing Staff and Patients under Treatment in Hospital for Other Diseases; a paper on Physical Culture and its Pitfalls, with a Critical Analysis of Swedish Drill, by Staff Surgeon A. Gaskell, R.N.; and another on Some Cases of Appendicitis treated at Haulbowline 1904 to 1906, by Fleet-Surgeon J. L. Barrington, R.N., Royal Naval Hospital, Haulbowline.

NURSING IN THE NAVY.

We have not yet enlisted the services of trained female nurses on battleships, and indeed our naval nurses form a small and comparatively unimportant body. In the United States Surgeon-General Rixey has just issued a plea for trained women nurses in the service, pointing out that in all modern wars the services of women nurses have proved of great value. In time of peace such nurses would secure for the sick at naval hospitals a better medical and surgical nursing service, he believed, than was now obtained and would be of great use in teaching and training the men of the hospital corps. In time of war they would be needed, in addition, for hospital ships, and their presence in hospitals would release a large number of hospital corps men for duty on board men-of-war. The recommendations of Surgeon-General Rixey for the establishment of a corps of trained nurses in the navy of the United States has, according to the *Nursing Times*, met with the approval of the Navy Department.

RUSSIAN WAR STATISTICS.

The *Broad Arrow* publishes in its issue of Jan. 19th some medical statistics of the Russian army lately officially published and quite correctly describes them as "curious reading." The period covered by the statistics embraces the whole period of the war, except the siege of Port Arthur and the combats in the island of Sakhaline (Sagallen), dating from February, 1904, to Jan. 1st, 1905. The following extract gives a very good idea of the nature of the figures. The admissions to hospital and deaths of officers are thus tabulated. Russian army: officers, sick and treated in hospital, 13,143 or 102 per cent.; cured, 8760, or 63 per cent.; sent to rear, 3264, or 25 per cent.; died, 210, or 1.6 per cent.; invalided, 57, remaining under treatment in the Far East, 663, or 6.9 per cent.; died from accidents, 10, or 0.078 per cent.; by suicide, 33, or 0.25 per cent. The deaths from "accidents" are thus classed: Alcoholism, 2 per cent.; drowned, 2 per cent.; railway accidents, 1.9 per cent.; and firearms, 0.09 per cent. Among the suicides 9 per cent. of the officers and 8 per cent. of the men took their lives by means of firearms.

The prize of £50 annually given by Sir John Cragg, M.V.O., to the London School of Tropical Medicine, for the investigator who makes the most valuable contribution to tropical medicine during the year, has just been awarded to Fleet-Surgeon P. W. Bassett-Smith, R.N.

Correspondence.

"Audi alteram partem."

EPSOM COLLEGE.

To the Editors of THE LANCET.

SIRS,—In a leading article dealing with the Benevolent Agencies of the Profession which appeared in THE LANCET of Jan. 12th you kindly referred in appreciative terms to the work carried out by the Royal Medical Foundation attached to Epsom College. As stated in the article, some foundation scholars practically owe all they possess to the help rendered by the College. Probably few of your readers are aware of what is the actual cost of educating and maintaining a foundation scholar. In some institutions where the standard of education is far below that provided at Epsom, and where the pupils leave at an earlier age, a child can be purchased into the school for a sum of approximately £200; but at Epsom College each foundation scholar who remains for the full time allowed by the by-laws costs between £700 and £800. Moreover, sons of medical men who pay the usual fees receive a substantial benefit, for, under the by-laws of the College, such boys are educated "at a sum as near to prime cost as reasonably may be."

In return, old Epsomians might do much for their alma mater if they would carry in their memory the needs of the foundation; and it would be a matter of great gratification if a large percentage of them would thus give practical evidence of loyalty and attachment to their old school. A few foundationers have contributed generously and there are doubtless others who, if the thought to do so occurred to them, are able and would be desirous to do likewise.

I should like to quote in *extenso* a letter just received from Australasia, the tone of which is most gratifying:—

DEAR SIR,—Herewith a draft for £5 10s. as a donation to the Benevolent Fund of your College. I sent you £5 last year. My intention is to send £31 10s. in all, being a guinea a year for each year I was able to practise. I am a chronic invalid from diabetes and heart trouble, therefore should I die before I have sent the whole £31 10s. my wife or family will send the balance.

Yours faithfully,

With this excellent example before them, those old Epsomians who have hitherto done nothing for the foundation of Epsom College may feel prompted to follow so admirable a lead. A donation of such a sum as would represent one guinea a year for each year the donor had been in practice would be a most welcome contribution to the funds, as well as a substantial expression of thanks for benefits received from the College. Coming now at a time when the funds of the foundation are severely depleted, owing to the extensive drainage and sanitary operations which cost £8000, such contributions would be doubly acceptable.

There are, of course, many old Epsomians who are not in a position to make any but small donations; and those who are unable to contribute themselves may yet be able to collect contributions. Under the by-laws of the College the same voting privileges are given for a collection of 20 guineas as for a donation of 10 guineas. As evidence of what can be done by medical men making appeals to others, I may mention that, in response to my letter in the medical press a few weeks ago, one medical man at once collected over £10, and an old Epsomian has lately obtained a grant of £500 from executors in whose hands a large sum of money had been left for disposal amongst charitable institutions.

I am, Sirs, yours faithfully,

HENRY MORRIS, Treasurer.

37, Soho-square, W., Jan. 16th, 1907.

THE PERSISTENCY OF THE INFECTION IN CERTAIN CASES OF SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—There was a very interesting short article in THE LANCET of Jan. 12th, p. 68, on the above subject. All medical men who have had much experience in the administration of fever hospitals must have frequently made the same observations as Dr. H. P. Berry of Grantham. The whole subject of "return" cases and persistency of infection

in scarlet fever is full of difficulties and the solution of the problem is at present shrouded in mystery. On the subject of "return" cases, which, of course, also has reference to the persistency of infection, in my last annual report I wrote as follows:—

Even after the most careful inquiries it is very difficult to satisfy one's self in a large number of instances that the child lately from hospital is the cause of the second case becoming infected and I am of opinion that many cases styled "return cases" are not return cases, in spite of the apparently strong presumptive evidence sometimes forthcoming; and my experience inclines me more and more to the opinion that just as the Klebs-Loeffler bacillus (the cause of diphtheria) may be found in the throats of people in perfect health, so the infection of scarlet fever, whatever it may be, may remain latent and only become active when the lowering of the body health from various reasons favours such increased activity of the infective matter as to cause the development of scarlet fever.

In other words, I am of opinion that many so-called "return" cases have become infected *before removal to hospital of the first case*, and the infecting organisms, whatever they may be, have remained latent until from some cause or other they have overcome the resisting powers of the patient *coincidentally with* the return of the other case from the hospital.

Let me give a very striking case bearing on this point. A child was sent into the Bootle Corporation Infectious Hospital notified as suffering from scarlet fever. She was admitted into the acute ward. On my examining her I discovered no signs of scarlet fever and I ordered her removal to the convalescent ward. The child remained in hospital for about five weeks, and after having remained perfectly well throughout her stay in the ward she was sent home. Within a week after her return home I received a notification that this same child was suffering from scarlet fever.

We have here an example of a child who had been in an acute scarlet fever ward for one day and a convalescent scarlet fever ward for over four weeks—that is to say, she had lived in an atmosphere impregnated with the infection of scarlet fever for five weeks and had remained quite well, probably because she had been kept clean and had been well fed and clothed; in other words, her resisting power had been kept up. When she returned home where her mode of life became less regular, where she was not so well fed—in other words, when her resisting power became lessened—the infection of scarlet fever, which must have been there all the time, developed. From the time of her discharge from the hospital until her return to the hospital she had not been out of doors nor had there been any visitors in the house, so that outside sources of infection might be excluded in this case. I have never met an instance which would support better than this the theory that the infection of scarlet fever may presumably remain latent as in diphtheria, and if the infection of the disease may remain latent in a healthy individual it may, of course, equally persist in an individual convalescent from the disease.

Again, which of us has not received into hospital a second case of scarlet fever from a house the day before or two days before the first case returned to that house from hospital? If circumstances had been reversed and Case No. 2 had been removed to hospital two days *after* instead of *before* the return home of the first case, Case No. 2 would definitely have been ascribed as being the result of infection from Case No. 1 in the absence of any other known cause of infection, even although Case No. 1 from outward appearances was as free from infection as a child could possibly be. Again, I think it is a common experience that it is precisely those cases which remain in hospital a long time which are the supposed causes of "return" cases. This may, of course, be that the clinical conditions which have necessitated the prolonged stay in hospital of any particular patient are precisely those which are the cause of infection in other children after they are discharged, though it may be that the result of the prolonged breathing of the infected atmosphere of a scarlet fever ward has been the accumulation in the nasal chambers or other places of the organisms causing the disease.

Whatever may be the explanation of "return" cases two facts are certain: (1) "return" cases more commonly result from the cases which have been treated for a long time in hospital than from those which have remained in hospital for shorter periods; and (2) the majority of "return" cases occur in the winter time when the weather is persistently unfavourable and the children are perforce kept in the wards continually breathing an infected atmosphere, and thus

cannot benefit from the disinfecting effects in the air passages of breathing the fresh air out of doors.

I am, Sirs, yours faithfully,

T. W. N. BARLOW,

Medical Officer of Health, Bootle.

Jan. 21st, 1907.

TYPHUS FEVER IN TENERIFFE.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to call attention in your columns to the above subject? It is officially admitted that typhus fever (or "plague," the authorities have not yet arrived at an exact diagnosis) exists in Teneriffe at the present time and I think it is right that the profession at home should know it. The epidemic is not an extensive one and, so far as I can ascertain, there have been only about a dozen cases, confined to Santa Cruz and its immediate neighbourhood. The careful traveller runs little or no risk of taking the disease, but the preposterous eccentricities perpetrated by the Spanish officials under the pretext of prophylaxis are enough to scare away any intending visitors and are calculated to afford them the maximum of trouble and inconvenience if they are bold enough to land.

Let me briefly relate the experiences of the party with whom I am travelling. We landed direct from England on Jan. 4th, 1907, and proceeded at once in carriages for Orotava. Each carriage bore a printed notice stating that it had been "disinfected" the same day, and the value of this disinfection may be estimated by the methods employed upon ourselves later. At Laguna we were turned out, led to an evil-smelling shed by the roadside, and a policeman pumped a spray of very dilute creolin solution over our boots and nether garments. No doctor was present. We smiled and passed on in fresh carriages, thinking the trouble was all over, but a very much more serious ordeal awaited us near Orotava. Here there was a large disinfecting station under the charge of two doctors, to whom I explained politely the circumstances of our journey and gave an assurance that we could not possibly have been in contact with any fever case or be conveying fomites in our luggage. But in vain. We were turned out again and this time literally drenched with fluid from a large garden syringe. The said fluid purported to be a solution of corrosive sublimate, but I received about half a drachm into my mouth and it tasted like nothing but dirty water, nor did it react at all on the metal fittings of our trunks. The gentlemen escaped fairly well, having hastily donned mackintoshes, but the ladies of the party were soaked to the skin in places and their dresses considerably damaged. Nor was this all; our wraps and trunks were sprayed and sponged copiously, with the result that the former were soaked through and the contents of the latter soiled and wetted, though the trunks themselves were not opened. All these proceedings were conducted with the exasperating deliberation and lack of method characteristic of the Latin races and finally, after the strenuous hygienists had disinfected an unfortunate pug dog which had strayed up from Orotava, we were allowed to depart amid the jeers of a crowd of loafers to whom our sufferings evidently afforded great satisfaction.

Such are Spanish methods of prophylaxis of infectious disease and one cannot but feel contempt for the authorities and medical officers who practise such ridiculous ineptitudes in the name of science. The folly of such proceedings must be obvious to anyone with the slightest knowledge of the disease and the manner in which it is disseminated. Of notification and the isolation of "contacts" I could hear nothing, and the only visible sign of disinfection was a sprinkling of chloride of lime round a house in which a fatal case had occurred at Laguna.

The important point is that this splendid health resort is being spoiled for invalids, on whom a soaking such as we got might have the most disastrous results. The excellent hotels at Orotava are not filling as they should and the companies which own them will suffer serious financial loss unless the authorities soon adopt saner and less objectionable methods. I would like to add that two years ago this ship was refused pratique except on the terms of a complete fumigation at Santa Cruz because we had three months before been in La Guayra—a supposed infected port—and in spite of the fact that we had since maintained a perfectly clean bill of health.

In conclusion I would repeat that visitors to Teneriffe

need not be unduly fearful of infection but must be prepared to face considerable loss and discomfort so long as the present sanitary reign of terror exists.

I am, Sirs, yours faithfully,

W. H. PELLE, M.D. Dub., D.P.H.

S.X. Erong, Santa Cruz, Tenerife, Jan. 6th, 1907.

SANITATION IN EGYPT.

To the Editors of THE LANCET.

SIRS,—May I offer some comments on the important and interesting letter of your Cairo correspondent on "The Drainage of Cairo" in THE LANCET of Dec. 22nd last?

What strikes a visitor interested in these matters is that the drainage of Cairo is only one item in the great problem of Egyptian sanitation. Your correspondent appears to imply that while there is a terribly high infantile mortality in Cairo, the health conditions in the villages are relatively good. It is to be feared that this is not the case. By all accounts the infantile mortality is everywhere enormous; one authority has repeatedly put it at two of every three children born. Certainly the conditions of water-supply and sewage in the villages are shockingly bad. Everywhere the drinking-water is obviously polluted in every conceivable way. Even in the small modern town of Helouan, a Cairo "health resort" on the edge of the desert, I have seen a pestiferous open channel, fortuitously formed, slowly carrying and depositing filth in one of the side areas. The water-supply of Helouan appears to be from wells, and in the porous desert soil percolation seems inevitable.

As to Cairo, it is to be noted that while the Anglo-Indian expert is preparing his report a number of streets are being laid with asphalt. This is in itself a desirable reform, but as the asphalt would have to be broken up again in case of a system of drainage being set up it is to be presumed that the Government do not contemplate such a system but have in view an extension or reform of the present method of removal by sanitary carts. If that be so, the time has clearly come for the development of such a system in the other towns and villages likewise. Your readers may remember that during the South African war Sir Arthur Conan Doyle made it a part of the case against the Boers that in their towns they had no drains. The British people should make the effort to realise that that is the state of things not only throughout the British colonies in South Africa—where it is justifiable—but throughout all Egypt (barring Alexandria) under British control. And even the Alexandria sewage system is very defective. The report of the Public Health Department for 1905 expressly ascribes the persistence of plague in Alexandria partly to the dilapidated state of the drains. Concerning the cesspools of Cairo, it may be true that some of the latest are well built; but the official reason given in the past for discontinuing the system of drainage begun before the occupation was that digging operations in Cairo were so often fatal to the diggers by reason of the infiltration of sewage from the existing cesspools. There is, I understand, no regular inspection of cesspools, no enforced law for their being periodically emptied, no limitation as to their size, and no requirement as to their being cemented.

It is to be feared that the explanation given by your correspondent of the long delay in filling up the open ditch in Cairo called the Khaliq—to the effect that the resistance came from Moslem fanaticism—is unduly favourable to the Government. The real reason seems to have been the official unwillingness to spend money on public health. What was finally done was to give the ditch as a concession to a tramway company on condition of their filling it up. They did so and laid a double tramway line on the narrow roadway they made, thus constituting the most dangerous thoroughfare in Cairo.

As to the present Cairo water-supply, on which your correspondent passes no judgment, I may mention that in the School of Police the drinking water is very carefully filtered, and the authorities are satisfied that this precaution has greatly raised their health standard. That is to say, the ordinary water is officially recognised to be bad. It is always discoloured at high Nile. Your readers can infer what are the chances for the rest of Cairo, with its population of nearly three-quarters of a million, and for the rest of Egypt, where the water-supply is still primeval, being generally taken from the Nile, or unprotected wells and canals, or stagnant pools.

Let me add that in Cairo there are only some five or six public latrines; that these are solely for men, and all in a small space in or near the Esbekieh Gardens; that they emit even in winter a great stench (one lately blew up from the gases generated beneath it); that natives can be seen in open day availing themselves (for all purposes) of the paths and walls in some of the principal tramway thoroughfares; that there are only some three or four drinking fountains, set up by pious Moslem donors; and that even in some modern streets may be seen pails or jars of unfiltered and sometimes dirty drinking water, charitably placed for the poor by Moslem householders. These jars commonly stand under the trees where filth accumulates. There are no public washhouses, nor public baths, apart from the impossible baths attached to the mosques—and this in a country where for six months of the year the climate is tropical. Yet another item. Flat tenements of five or even of six storeys are now being rushed up, though many complaints are made in the newspapers that the pressure is often hardly enough to take the water to the second floors. I say nothing as to inspection of milk-supply which, I fear, is much needed.

I am, Sirs, yours faithfully,

Cairo, Jan. 10th, 1907.

JOHN M. ROBERTSON.

MILK IN SMALL GENERAL SHOPS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 19th, p. 193, I notice an article from a correspondent on "Milk in Small General Shops." As to the unsuitability of the majority of such premises for the sale of milk there can be no difference of opinion, but the statement that 70 per cent. of the milk-supply of London is retailed from such shops is, I think, erroneous and should therefore not be allowed to pass without comment. Surely the dairymen of London are responsible for more than 30 per cent. of its milk-supply.

I have recently been inquiring into the subject in this borough and enclose you the result of my investigations. It will be seen that while 57 dairies sell 2250 gallons of milk daily, an average of nearly 40 gallons per dairy, 69 small general shops such as described by your correspondent sell but 70 gallons daily, an average of practically only one gallon per shop. If the conditions prevailing here are similar to those in the East of London—and I think such may fairly be claimed to be the case—the percentage of milk sold by these shops, grossly polluted though such milk must be, is fortunately not nearly so large as is stated by your correspondent. With the rest of the paper I cordially agree and also fully endorse the opinion expressed as to the large amount of condensed milk that is given to children, especially in poor neighbourhoods, such condensed milk, moreover, as my inquiries show, being only too often the condensed skimmed variety.

I am, Sirs, yours faithfully,

G. SOWDEN,

Medical Officer of Health for the Borough of East Ham.

Jan. 21st, 1907.

GAS FIRES.

To the Editors of THE LANCET.

SIRS,—Will you allow me space for a short reply to the letter from Mr. J. H. Brearley which appeared in THE LANCET of Jan. 12th? In that letter the author takes the unusual course of quoting without my permission portions of a correspondence I had with him last year on the subject of gas fires; and while I wrote nothing to Mr. Brearley that need not be published I object to isolated sentences being chosen for reproduction and still more to what Mr. Brearley "gathers" from my letters. Thus, he gathers from what I wrote "that the gas fire was fitted into the same flue as the coal fire without any consideration as to the satisfactory carrying away of the products." Yes, it was fitted into the same flue as the coal fire. Is not that done in nine cases out of ten? Is it not the "ordinary way"? And that was therefore the case I wished to examine. Mr. Brearley goes on to say that I paid no consideration as to the satisfactory carrying away of the products. Now I stated in my pamphlet that the "stove worked perfectly well," and this, of course, includes the carrying away of the products of combustion. Mr. Brearley seems to forget that I undertook a serious investigation, that I devoted 15 months to the work, that I obtained concordant results,

in scarlet fever is full of difficulties and the solution of the problem is at present shrouded in mystery. On the subject of "return" cases, which, of course, also has reference to the persistency of infection, in my last annual report I wrote as follows:—

Even after the most careful inquiries it is very difficult to satisfy one's self in a large number of instances that the child lately from hospital is the cause of the second case becoming infected and I am of opinion that many cases styled "return cases" are not return cases, in spite of the apparently strong presumptive evidence sometimes forthcoming; and my experience inclines me more and more to the opinion that just as the Klebs-Loeffler bacillus (the cause of diphtheria) may be found in the throats of people in perfect health, so the infection of scarlet fever, whatever it may be, may remain latent and only become active when the lowering of the body health from various reasons favours such increased activity of the infective matter as to cause the development of scarlet fever.

In other words, I am of opinion that many so-called "return" cases have become infected *before removal to hospital of the first case*, and the infecting organisms, whatever they may be, have remained latent until from some cause or other they have overcome the resisting powers of the patient *coincidentally with the return of the other case from the hospital*.

Let me give a very striking case bearing on this point. A child was sent into the Bootle Corporation Infectious Hospital notified as suffering from scarlet fever. She was admitted into the acute ward. On my examining her I discovered no signs of scarlet fever and I ordered her removal to the convalescent ward. The child remained in hospital for about five weeks, and after having remained perfectly well throughout her stay in the ward she was sent home. Within a week after her return home I received a notification that this same child was suffering from scarlet fever.

We have here an example of a child who had been in an acute scarlet fever ward for one day and a convalescent scarlet fever ward for over four weeks—that is to say, she had lived in an atmosphere impregnated with the infection of scarlet fever for five weeks and had remained quite well, probably because she had been kept clean and had been well fed and clothed; in other words, her resisting power had been kept up. When she returned home where her mode of life became less regular, where she was not so well fed—in other words, when her resisting power became lessened—the infection of scarlet fever, which must have been there all the time, developed. From the time of her discharge from the hospital until her return to the hospital she had not been out of doors nor had there been any visitors in the house, so that outside sources of infection might be excluded in this case. I have never met an instance which would support better than this the theory that the infection of scarlet fever may presumably remain latent as in diphtheria, and if the infection of the disease may remain latent in a healthy individual it may, of course, equally persist in an individual convalescent from the disease.

Again, which of us has not received into hospital a second case of scarlet fever from a house the day before or two days before the first case returned to that house from hospital? If circumstances had been reversed and Case No. 2 had been removed to hospital two days *after* instead of *before* the return home of the first case, Case No. 2 would definitely have been ascribed as being the result of infection from Case No. 1 in the absence of any other known cause of infection, even although Case No. 1 from outward appearances was as free from infection as a child could possibly be. Again, I think it is a common experience that it is precisely those cases which remain in hospital a long time which are the supposed causes of "return" cases. This may, of course, be that the clinical conditions which have necessitated the prolonged stay in hospital of any particular patient are precisely those which are the cause of infection in other children after they are discharged, though it may be that the result of the prolonged breathing of the infected atmosphere of a scarlet fever ward has been the accumulation in the nasal chambers or other places of the organisms causing the disease.

Whatever may be the explanation of "return" cases two facts are certain: (1) "return" cases more commonly result from the cases which have been treated for a long time in hospital than from those which have remained in hospital for shorter periods; and (2) the majority of "return" cases occur in the winter time when the weather is persistently unfavourable and the children are perforce kept in the wards continually breathing an infected atmosphere, and thus

cannot benefit from the disinfecting effects in the air passages of breathing the fresh air out of doors.

I am, Sirs, yours faithfully,

T. W. N. BARLOW,
Medical Officer of Health, Bootle.

Jan. 21st, 1907.

TYPHUS FEVER IN TENERIFFE.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to call attention in your columns to the above subject? It is officially admitted that typhus fever (or "plague," the authorities have not yet arrived at an exact diagnosis) exists in Tenerife at the present time and I think it is right that the profession at home should know it. The epidemic is not an extensive one and, so far as I can ascertain, there have been only about a dozen cases, confined to Santa Cruz and its immediate neighbourhood. The careful traveller runs little or no risk of taking the disease, but the preposterous eccentricities perpetrated by the Spanish officials under the pretext of prophylaxis are enough to scare away any intending visitors and are calculated to afford them the maximum of trouble and inconvenience if they are bold enough to land.

Let me briefly relate the experiences of the party with whom I am travelling. We landed direct from England on Jan. 4th, 1907, and proceeded at once in carriages for Orotava. Each carriage bore a printed notice stating that it had been "disinfected" the same day, and the value of this disinfection may be estimated by the methods employed upon ourselves later. At Laguna we were turned out, led to an evil-smelling shed by the roadside, and a policeman pumped a spray of very dilute creolin solution over our boots and nether garments. No doctor was present. We smiled and passed on in fresh carriages, thinking the trouble was all over, but a very much more serious ordeal awaited us near Orotava. Here there was a large disinfecting station under the charge of two doctors, to whom I explained politely the circumstances of our journey and gave an assurance that we could not possibly have been in contact with any fever case or be conveying fomites in our luggage. But in vain. We were turned out again and this time literally drenched with fluid from a large garden syringe. The said fluid purported to be a solution of corrosive sublimate, but I received about half a drachm into my mouth and it tasted like nothing but dirty water, nor did it react at all on the metal fittings of our trunks. The gentlemen escaped fairly well, having hastily donned mackintoshes, but the ladies of the party were soaked to the skin in places and their dresses considerably damaged. Nor was this all; our wraps and trunks were sprayed and sponged copiously, with the result that the former were soaked through and the contents of the latter soiled and wetted, though the trunks themselves were not opened. All these proceedings were conducted with the exasperating deliberation and lack of method characteristic of the Latin races and finally, after the strenuous hygienists had disinfected an unfortunate pug dog which had strayed up from Orotava, we were allowed to depart amid the jeers of a crowd of loafers to whom our sufferings evidently afforded great satisfaction.

Such are Spanish methods of prophylaxis of infectious disease and one cannot but feel contempt for the authorities and medical officers who practise such ridiculous ineptitudes in the name of science. The folly of such proceedings must be obvious to anyone with the slightest knowledge of the disease and the manner in which it is disseminated. Of notification and the isolation of "contacts" I could hear nothing, and the only visible sign of disinfection was a sprinkling of chloride of lime round a house in which a fatal case had occurred at Laguna.

The important point is that this splendid health resort is being spoiled for invalids, on whom a soaking such as we got might have the most disastrous results. The excellent hotels at Orotava are not filling as they should and the companies which own them will suffer serious financial loss unless the authorities soon adopt saner and less objectionable methods. I would like to add that two years ago this ship was refused pratique except on the terms of a complete fumigation at Santa Cruz because we had three months before been in La Guayra—a supposed infected port—and in spite of the fact that we had since maintained a perfectly clean bill of health.

In conclusion I would repeat that visitors to Tenerife

the enamel is largely formed before artificial feeding is commenced. Mr. C. S. Fomes in his "Dental Anatomy" writes, "the first temporary molars are complete as to their maturing surfaces" at birth. As these are perhaps the teeth of the temporary set which succumb first and most rapidly to dental caries, it is impossible to attribute this to defective development or to any predisposition to decay in the tooth itself as a result of artificial feeding. Now this is important, as about 99 per cent. of children at the age of five or six years have dental caries in several teeth, of which the first temporary molar is almost invariably one. Again, children who are fed physiologically after the artificial feeding of the first year invariably, so far as my observations go, have teeth free from dental caries. I have come across a few examples of this, although as physiological feeding, having regard to the consistency of the food and the arrangement of the meal, is so generally unknown such examples are rarely to be found. With regard to the permanent teeth which may be affected by artificial feeding, it would appear that the evidence is but slight in support of the supposition that it has an injurious effect on the development or structure of the teeth. It would appear rather that some severe constitutional disturbance, the result of mal-environment, is generally responsible for the defective structure when it exists, though occasionally grossly improper feeding and consequent ill health may be presumed to have a like effect. Mr. Sidney Spokes has made a valuable contribution to this subject. He finds that in one of our public schools 4.6 per cent. of the boys had hypoplasia—i.e., defective development of the enamel in the permanent teeth—while in the Poor-law schools the percentages were 7.1 for the boys and 7.5 for the girls. The statistics are not mentioned as to the relative number of breast-fed children in either group, but notwithstanding their greater freedom from hypoplasia it may be presumed that the boys of the public school were less frequently breast fed than the boys and girls of the Poor-law schools. Corroborative evidence of like nature is, I think, to be found in the investigation undertaken by Mr. J. H. Gibbs and Mr. G. W. Watson, recently recorded by Dr. Chalmers Watson in *THE LANCET*. With regard to Dr. Creswell's second question, it is no doubt the case that the teeth of bottle-fed children do decay more early and rapidly than those of breast-fed children, not, as a rule, because the teeth are in the least defective, but because such children are usually kept longer and more exclusively on the bottle than breast-fed children are kept at the breast. Moreover, having acquired in all probability a delicate digestion the result of artificial feeding, they are kept more strictly on a diet in which a more or less starchy artificial food is substituted for, or added to, cows' milk, in order to prevent curdling and the dyspeptic troubles which might follow. Such bottle-fed children are also likely at a later age to be kept more strictly to a diet in which the bread or rusks, &c., are carefully "well soaked" in the milk for like reason. To this may be added the fact that an artificially fed baby occasionally develops rickets after it is a year or two old, and then, instead of being given a little fish or chicken, or vegetable, or fresh fruit to supplement its daily dietary, the rickety child probably has more frequently its milk soaked diet supplemented by raw meat juice and perhaps fruit juice. Lastly, there is no doubt that on the average the breast-fed child thrives best, the teeth are put to better use and are not bathed in vitiated secretions. The jaws grow normally, the teeth become less crowded, and altogether they have a better chance of being subjected to those natural processes which normally prevent dental caries.

I am, Sirs, yours faithfully,

Wimpole street, W., Jan. 19th, 1937.

J. SIM WALLACE.

SPIROGRAPHS OR NASAL "BREATH PICTURES."

To the Editors of *THE LANCET*.

SIRS,—The practice of testing nasal patency by breathing upon a prepared surface is by no means new, but its usefulness has been somewhat restricted by the want of a satisfactory material. Slate, glass, and polished metals all have their shortcomings, but I have now found that vulcanite with a medium polish gives a very reliable and faithful image. By placing the plate horizontally on the upper lip half an inch from the nostrils and giving one short and steady expiration a well-defined steam impression results, which can

evaporating affords reliable and striking evidence of the actual and relative patency of the nostrils. The image may be temporarily fixed or rendered more conspicuous for demonstration purposes by lightly powdering it with calcined magnesia or fine starch. Small sheets of vulcanite with a suitable surface and of a convenient size are supplied by the Medical Supply Association, 238, Gray's Inn road, London, W.C.

I am, Sirs, yours faithfully,

WYATT WINGRAVE, M.D. Durb.

Central London Throat and Ear Hospital, Jan. 19th, 1937.

THE PAST AND PRESENT INCIDENCE OF INFECTIOUS DISEASE.

To the Editors of *THE LANCET*.

SIRS,—I agree with Dr. H. E. J. Bies in saying we can never expect to see the full benefit resulting from notification and isolation till the whole country has gone through a systematic sanitary inspection. The correction of existing sanitary defects would mean the breaking up of the germ-breeding grounds, and we should thus be dealing with the prime cause of infectious disease. A supply of pure air, pure water, and pure food in any district cannot do otherwise than bring about a general increase of vitality, or, in other words, increased powers of resistance.

I am, Sirs, yours faithfully,

Bexhill-on-Sea, Jan. 21st, 1937.

F. P. ATKINSON.

MILK IN SMALL GENERAL SHOPS.

(FROM A CORRESPONDENT.)

II.

IN my previous article dealing with the manner in which milk is retailed in small general provision shops, I described somewhat briefly a few shops of this kind into which I entered to observe the conditions. As pointed out, in none of these were the conditions favourable for keeping milk in a fit state to serve as a food for young children, and in some of the shops the surroundings were so insanitary as in certain circumstances to render the milk absolutely dangerous as a food for infants. It is not only in the East-End of London that small general provision shops in which milk is retailed are prevalent. They abound in every part of London in which the poor are massed, and undoubtedly are the means of supplying this class with the greater portion of the raw milk which they and their families consume. In the course of my limited tour of inspection I visited several localities in and about London, populated chiefly by the working classes, and found, as in the East-End, that public-houses and small general provision shops were everywhere conspicuous. A description of such a shop in Holborn or in St. Pancras, or even in a suburban district, is in most essential details similar to that of one in the East-End. They differ only in degree. Almost all are small, many by no means clean, and packed with a miscellaneous store of eatables and of articles for domestic use. In perhaps the majority of these establishments the milk is kept either uncovered or partially uncovered, the dipper is exposed to contamination by outside agencies, the door of the shop is frequently kept open in hot weather, always thrown back, permitting the dust and dirt from the street to blow in freely; in short, most precautions calculated to protect the milk from pollution are neglected. Again, the mode in which the milk when bought is conveyed from the shop to the home is, as a rule, characterised by great carelessness. In many instances a child is sent with a jug or other open receptacle in itself often unclean and to which dust and dirt of every description have ready access. Into the question of the extent to which milk is open to contamination in the homes of the poor there is no need to enter here, although undoubtedly this source of pollution is a potent factor in the causation of infantile mortality and one which must be grappled with ere the successful, or partially successful, solution of the problem of how to insure a comparatively pure milk-supply to the young children of the poor is in sight.

¹ The first article was published in *THE LANCET* of Jan. 19th, 1937, p. 193.

and that I published both the detailed and average results. He seems to think that I started, not with the object of ascertaining the truth, but to justify some preconceived opinions and that for this purpose I used an unsuitable stove "probably badly fitted to the flue." What right has Mr. Brearley to say of a fixture he has not seen that it is probably bad, unless, indeed, he implies that all gas fires are badly fitted? In that case my results are still of value.

Mr. Brearley is surprised that I did not record the temperature of the room during the experiments. This did not come within the scope of my investigation, which was directed entirely to the effect produced on the composition of the air by various methods of heating and lighting. He also objects to the size of room I used, forgetting that gas fires are often used in small rooms and, still worse, gas-cooking stoves in still smaller sculleries.

Finally, I object to Mr. Brearley's interpretation of my motives. It is true that he says he would be the last to "impute other than the highest motives" to me, but that is quite neutralised by such statements as the following: "I must say that if you had been endeavouring to get the percentage of carbonic acid in the atmosphere as high as possible you could not have adopted better conditions." Mr. Brearley forgets that I hold no brief either for gas or electric lighting companies, that I should have published the results in any circumstances, whether in favour of gas or coal fires, and I may tell him that as a consequence of the experiments I at once introduced the electric light in my own house. I am sorry to find that the editor of the *Electrical Engineer* by expressing his confidence in the accuracy of my work is sneered at by Mr. Brearley—his "wish is father to the thought."

When Tennyson found his poems adversely reviewed by Christopher North he replied somewhat as follows (I quote from memory):—

You did once review my lays,
You did mingle blame with praise,
When I learned from whom it came
I forgave you all the blame,
I could not forgive the praise,
Crusty Christopher.

So I feel with regard to Mr. Brearley, I cannot forgive his praise when he accompanies it with attacks on my good faith in carrying out the investigation on the air of rooms.

I am, Sirs, yours faithfully,

FRANCIS JONES, M.Sc., F.R.S.E., F.O.S.

Manchester, Jan. 19th, 1907.

SPECIFIC GRAVITY OF URINE.

To the Editors of THE LANCET.

SIRS,—Although many may be aware of the abstract fact that the specific gravity of all liquids varies with the temperature it may not be generally appreciated, as a concrete example, that the specific gravity of urine is very materially influenced by temperature. Probably in the great majority of cases specimens of urine are examined when it has become cooled—i.e., when it is at the temperature of the surrounding air, since these specimens generally reach one in bottles, which are allowed to stand some little time, but I have frequently had occasion to examine urine which has been freshly passed, notably in cases of examination for life insurance, when it is passed at the time of examination.

I have often been struck with the low specific gravity of such freshly passed urine in many cases of young and healthy lives and was disposed to attribute it to the influence of the ingestion of fluid previous to the examination. On one occasion, lately, a specimen showing a specific gravity of 1015, when freshly passed, was left standing over night, with the urinometer *in situ*. On looking at it next day, before emptying the test glass, I was surprised to find the specific gravity to be 1020, thus showing a rise of five points. My attention being thus directed to this discrepancy, I made a series of observations, noting the temperature and specific gravity of the urine when it was freshly passed, and, later, when it had cooled down to the temperature of my surgery. As a result I find that the specific gravity of urine varies inversely with the temperature and that it rises, on an average, one point for every fall of eight degrees of temperature. I find no allusion to this in any text-book of physiology or clinical medicine, and I consider the recognition of the fact is of

importance, and it is a fact which can be easily verified, inasmuch as it should conduce to the prevention of fallacy in estimating the specific gravity of urine. Urine which at 60° shows a specific gravity of 1020, will at 96° show a specific gravity of only 1015.

I am, Sirs, yours faithfully,

ALEX. THEODORE BRAND, M.D., C.M. Aberd.

Driffield, East Yorks., Jan. 19th, 1907.

MEAT DIET AND THE TEETH.

To the Editors of THE LANCET.

SIRS,—In connexion with the correspondence which has appeared in your columns upon this subject over the signatures of Dr. J. Sim Wallace, Dr. D. Chalmers Watson, and Mr. J. H. Gibbs, I should like to state that in the specimens shown at the Pathological Society on Dec. 18th, 1906, a distinct difference was apparent between a tooth germ in the meat-fed and one in the bread-and-milk-fed animal. The section of the head of a meat-fed rat, thrown upon the screen in order to demonstrate the bone changes, showed a developing tooth which was not a normal one. The vascular papilla, the odontoblasts, and the ameloblasts were poorly and irregularly developed. The contrast between this germ and that of a normal rat was well displayed in Dr. Chalmers Watson's excellent preparations. This specimen may, of course, have been from one of the three animals referred to in Mr. Gibbs's letter in which the erupted teeth were of the honeycomb variety. Nevertheless, it would be of interest to know whether the enamel organs and dental papillae were found to be normal in the other meat-fed rats.

At that meeting of the Pathological Society I suggested, as reported in THE LANCET of Dec. 29th, 1906, that Dr. Chalmers Watson was mistaken in ascribing many of the effects observed by him to a meat diet and that they were probably due to a deficiency of lime and other bases, as no bone or bone dust was given with the meat. The perusal of Dr. Chalmers Watson's letter in THE LANCET of Jan. 12th leads me to add that until this point is settled any deductions from the experiments as to the effects of meat-eating habits upon the physique of the present generation seem to me to be premature. Indeed, whether the results produced in rats are due to the want of lime and other bases or whether they are an expression of the failure of a naturally omnivorous animal to rapidly adapt itself to a purely flesh diet it is clear that they cannot be directly applied to the case of civilised man, who never in ordinary circumstances lives upon a diet of meat alone. A mixed diet may contain a very large proportion of meat and yet be not wanting either in carbohydrate or fat or in the necessary inorganic elements present in vegetables, fruits, milk, and in the drinking water of many districts.

I am, Sirs, yours faithfully,

EDMUND I. SPRIGGS.

London, W., Jan. 21st, 1907.

To the Editors of THE LANCET.

SIRS,—In his letter of Jan. 19th Dr. W. G. Creswell asks whether the artificial feeding of infants prejudicially affects the teeth. For several years, during which I have examined about 5000 hospital dental patients annually, I have directed special attention to this subject and have satisfied myself that the artificial feeding of children as generally carried out does exert a harmful effect on the development of the teeth, a view which is in accord with that generally held by dental surgeons. This harmful effect is shown in structural defects of the tissues and in irregularity of the teeth, conditions which favour the lodgment of food and subsequent caries.—I am, Sirs, yours faithfully,

J. H. GIBBS.

Edinburgh, Jan. 21st, 1907.

To the Editors of THE LANCET.

SIRS,—In his letter to THE LANCET of Jan. 19th Dr. W. G. Creswell asks two important questions which have not been answered by all authorities in the same way. Nevertheless the evidence is sufficiently strong, I think, to justify us in saying that the artificial feeding of infants *per se* does not prejudicially affect the development or structure of the teeth. The teeth of children, whether breast fed or otherwise, are almost invariably perfectly good to all external appearances when they cut the gums. Only about 6 per cent. have somewhat defective enamel; but this defective formation of the temporary teeth cannot be

FIG. 1.

Roofed court uniting two pavilions intended for cattle pens.

FIG. 2.

Scene at the Vaugirard Abattoir; the soot-black walls should be noted.

So far, however, as the milk-supply of the London poor is concerned, regarded solely from the point of view of the small general provision shops' supply, my observations, cursory though they were, have taught me these facts, which, of course, have been made the subject of comment before: That the working classes obtain the greater part of, if not almost all of, the raw milk which they and their families consume at small general provision shops; that in most of these shops the sanitary conditions are unfavourable, milk being kept in such a state as to render it an injurious food for infants; and that in a large number of cases precautions to preserve the milk from pollution are neglected both by the small shopkeepers and the customers. The menace to infant life involved by impure milk is too well known to require emphasis. During the year 1904 about 19,000 infants under one year of age died in London. Of this number no less than 2347 died from epidemic diarrhoea, the largest number who died from any one cause. It is needless to state that the occurrence of epidemic diarrhoea amongst infants is attributed to improper nourishment, chiefly to impure milk. Vaughan goes so far as to assert that nearly all cases of summer diarrhoea among infants are due to the presence of putrefactive or other bacteria of decomposition in the milk. I am only recapitulating the fact that milk which has undergone certain fermentative changes, or which has been polluted by dirt of any description or by flies, is especially dangerous as a food for infants, a matter now of almost general knowledge, in order to press home the point that the manner in which the milk-supply of London is controlled is susceptible of much improvement and that the milk provided for the infants of the poorer classes should be of the best possible quality.

The small general provision shops of London play a very important part in the scheme of providing its poor inhabitants with milk, and therefore if these establishments are to be allowed to continue to supply milk they should at least be managed in such a way that all unnecessary contamination may be avoided. When making my observations I entered a few of the regular milk shops both in the East-End of London and in other metropolitan districts inhabited by poor people. I found that in these shops adequate precautions to preserve the milk from contamination were well observed. Why then do not the poor avail themselves of the opportunities thus afforded to obtain milk which is guarded from the pollution to which it is subjected in the small shops? The reasons probably are that the small shops are more convenient for them, that they can buy the milk they require when they buy their other provisions, and, lastly, that they can obtain credit at the shops at which they are accustomed to deal. Ignorance, too, in regard to the dangers of contaminated milk, on the part of the London mother of the lower class, is a weighty feature of the situation and one which has a great bearing on the sickness and mortality of infants.

The London County Council makes regulations dealing with the cleanliness of milk stores, milk shops, and milk vessels and the precautions against infection to be taken by the purveyors of milk and by persons selling milk by retail. These regulations are enforced by the metropolitan borough councils which are also required to register all persons carrying on the trades of cowkeepers, dairymen, or purveyors of milk. In Shoreditch, at the end of 1904 there were on the register 294 shops the proprietors of which were licensed to sell milk. During 1904 3199 inspections were made. In Holborn during the same period there were 171 such shops, and 1160 inspections were made. In Shoreditch the inspections seem to have been numerous, but I can only state that the small provision shops selling milk which I visited in that district certainly did not observe precautions necessary to preserve the milk from pollution, nor, indeed, in any locality to which I went did I find these shops in such a condition as to conform in any respect to one's ideas of what a milk shop should be. I may have been unfortunate in the selection of shops but I am of the opinion that a deplorable laxness is the rule rather than the exception in the management of small general provision shops in London in which milk is sold. The sale of milk in provision shops is but one phase of the milk question. It is, nevertheless, an important phase and is well worth investigation and discussion. The desideratum in regard to milk is that the poor should be able to procure it at the same time good and cheap. It is argued, and doubtless with truth, that if all the precautions needful to insure a pure milk-supply were enforced the cost of the product would be greatly

increased. If, for example, as in New York and in some other American cities, certified milk were supplied on request the various methods through which such milk has to go in order to reach the high standard required would render it necessary to increase the price. Obviously a milk of this description would be unattainable by the poor even if they were educated up to the point of appreciating its value. In the meantime it would be a decided step in the right direction if the proprietors of small provision shops who retail milk were compelled to observe certain well-defined precautions, such as keeping all the milk vessels scrupulously clean and having the milk in a vessel which should be always covered and provided with an exit tap so as to prevent dirt and flies to some extent from contaminating the milk.

THE PARIS ABATTOIR AT LA VILLETTE.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from p. 126.)

THERE are at La Villette 11 pavilions such as have been described and illustrated where sheep and horned cattle are slaughtered. Other pavilions very similar in structure and united by a central glass-roofed court are used as cattle-pens where the animals which have been brought from the neighbouring cattle market wait till it is their turn to be slaughtered. These pavilions, however, are so utterly unsuited for the purpose, so deficient in light and ventilation, that the same thing happens there as occurs in regard to the slaughtering. The cattle, especially during the hot summer weather, are kept in the glass-roofed yards instead of in the pavilions on each side of the yards. (See Fig. 1.) Here they have plenty of light and air, but there are no mangers, no water troughs—in fact, no stable appurtenances. Also it is much easier for the veterinary surgeons to examine them in the yards than in the neighbouring dark stables. Thus, just as the butchers like to work in the open court instead of in their small private compartments, so also are the cattle kept in the courts between the masonry pavilions rather than in the pavilions themselves. This is a very practical demonstration of the unsuitability of the latter. I did, however, penetrate some of these buildings and found them very dark and repugnant. In one of them there were a number of sheep separated by wooden partitions well calculated to retain dirt and disease germs. Also, and apart from these pavilions, I saw some small brick structures used for keeping sheep. In these latter there were numerous rafters and only very small windows which supplied but little air or light.

Further on there are extensive wooden stables for sheep which, though built 12 years ago, were called provisional. Here the central passage is so narrow that the manure has to be thrown out of the windows. A cart or even a hand barrow could not be introduced inside the building. But it is especially deplorable that no idea seems to exist as to what ought to be done. Thus the principle that wood, being porous, is an unsuitable material to employ has not dawned upon the workers and butchers of La Villette. On the contrary, if there is a need of some sort of railing or partition, an attendant is almost sure to explain how with a few planks or a pole this can be provided. Therefore the sheep and other animals are only separated from each other by wooden framework which becomes black and greasy and caked with dirt, thus supplying a culture medium for microbes. This may help to account for the frequent cases of foot-and-mouth disease which occur at La Villette. The large wooden stables were built at a time when a great quantity of German sheep were imported into Paris. They cost, it appears, no less than £16 000.

This wooden structure is not of much use to-day, as there are no longer many sheep imported from Germany. It is situated close to the Ourcq canal and a rising bridge enabled the sheep to go from the cattle market into the slaughter-house without leaving the railway tracks that had brought them from Germany. All this is very badly organised, there are no proper platforms for the landing of the sheep, and it is no use sending animals, already purchased for killing, to the cattle market where they come in contact with, and may infect, other cattle. Worse, if anything, than the improper structure of many of the buildings is the fact that the water-supply at La Villette is insufficient. The water main is only 30 centimetres in diameter and there are moments when this does not suffice, so that the taps

the land was originally acquired it was intended to erect upon it houses for working men at a rental of 5s. per week or less. In the event, however, it proved impossible to devise a scheme whereby such houses could be built and maintained except at the expense of the rates, and the council wisely refused to have anything to do with the creation of municipal buildings, having in view the want of success which had attended similar ventures in other places. Moreover, it is questionable if at the present time houses of the class originally proposed would really be useful if erected on the Bordesley Green site. By deciding to hand over the land to the Ivy Benefit Society under certain terms the council has sanctioned the attempt to develop on a site of about 28 acres a garden city within the city boundaries. It is true that the houses to be erected will somewhat exceed 5s. a week in rental, but it is also obvious that the rents cannot be high, for 50 per cent. of the members of the society which is to develop the site earn wages of 30s. a week or less. If the calculations have been well made the experiment will eventually be a profitable one for the city and possibly may do something to aid in the diminution of the already too heavy rates. From the public health point of view the experiment is of the utmost importance and if it is successful it may prove to be the beginning of a satisfactory solution of numerous housing difficulties which now beset the guardians of great cities.

A New Children's Hospital.

A committee has been formed to draw up a scheme for the building and endowment of a new children's hospital for Birmingham.

A New Poor-house Infirmary for Aston.

The overcrowding of the workhouse at Aston and the refusal of the Local Government Board to allow additions to be made to it have necessitated the utilisation of the present infirmary for the accommodation of the ordinary inmates and consequently the provision of a new infirmary. It is proposed to acquire some additional land adjoining the workhouse ground and to erect upon it a new infirmary capable of receiving 900 patients. On the whole, the scheme seems the most economical one which could be adopted, for as the new infirmary will be in the immediate neighbourhood of the workhouse the present nurses' home will be still available and the management during the transition period will be rendered comparatively easy. Before it can be carried out, however, the Local Government Board must be consulted and an application is to be made for its consent to the scheme and the necessary expenditure.

Wolverhampton Water-Supply.

The available supply of water at Wolverhampton is at present about 4,000,000 gallons per day and the governing officials think it necessary to increase the supply in view of increasing necessities. It is proposed to sink a series of boreholes to a depth of 1000 feet in an area which has been explored, and to meet the expenses already incurred and those which erection of the required buildings, pumping stations, and reservoirs will entail it will be necessary to borrow £90,000. It is estimated that for this sum the water-supply will be increased by a million and a half gallons a day.

Jan. 22nd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The City and the University of Liverpool.

THE accounts of the University for the year ending Sept. 30th, 1906, were passed at the annual meeting of the court of governors, and in themselves afford strong proof of the growth and strength of the University. From the balance-sheet it appeared that the total assets of the University were something over £735,000, represented very largely by the value of sites and buildings and investment of endowed chairs and laboratories. The receipts for the year were over £61,000, made up chiefly of grants from Government and public bodies, amounting altogether to £26,000, interest on investments £9500, and fees from students £15,500. On the expenditure side of the account the chief items were for salaries of professors, lecturers, and teachers £21,000, and general expenses (including salaries of office staff) £12,000 in each case ignoring odd figures. The balance

of income over expenditure was very small, but it should be pointed out that for the first time this year a substantial sum has been set apart for repairs and renewals of buildings, a very wise step which should lead to the gradual collection of an adequate reserve fund for those necessary expenses which will increase in the future as the buildings grow older. On the whole, the accounts may be considered extremely satisfactory and afford evidence of careful and business-like administration.

The Hospital Sunday Fund Collection.

Collections in aid of the medical charities of Liverpool were taken on Jan. 13th in the various places of worship throughout the city and suburbs. The largest sum collected was £590 at the Ullet-road Unitarian church. Sefton Park Presbyterian church came next with £559. The treasurer of the fund has just published the first list of collections, and it will be satisfactory to note that there is an increase of £627 over that of last year.

Liverpool Health Committee: Sterilised Milk and the Infantile Death rate.

For the past week the birth-rate was 41.2 per 1000 of the estimated population of 746,144 and the death-rate 22.7 per 1000, as compared with 21 per 1000 a year ago. The infectious cases in hospital comprised: small-pox, three; scarlet fever, 418; typhus fever, ten; typhoid fever, 36; measles, 24; diphtheria, 48; in isolation, 67; total, 606. Reference was made to the splendid results which had followed the use of sterilised milk in the city. It was stated that the death-rate of infants supplied with the milk by the corporation was something like 84 per 1000, whereas the rate of mortality amongst infants fed with ordinary milk was 158 per 1000.

The Duchess of Albany and the Liverpool School of Tropical Medicine.

Her Royal Highness the Duchess of Albany paid a private visit to the School of Tropical Medicine prior to the opening of the Children's Infirmary last week. She was accompanied by the Earl of Derby and her suite and was received at the University buildings by Vice-Chancellor Dale and other gentlemen. Upwards of an hour was spent in the laboratories of the school. Professor Ronald Ross acted as guide and expositor to Her Royal Highness, and Dr. A. Breinl and Dr. J. L. Todd assisted in exhibiting under the microscope the varied specimens of malarial which germinate and distribute the diseases of the tropics. The cancer research and experimental sections were also visited. This was the fourth occasion in which the School of Tropical Medicine has entertained royalty during the six years of its existence, other Royal personages who have honoured it by their presence being the Princess of Wales, Princess Christian, and Princess Victoria. Her Royal Highness's autograph was secured for the album of the Guild of University Undergraduates.

The Liverpool Royal Infirmary.

At a special meeting of the election committee held on Jan. 15th Dr. John Hay, honorary physician to the Stanley and Consumption Hospitals, was appointed assistant physician in the room of Dr. E. E. Glynn, who resigned that appointment upon his election to the post of deputy professor of pathology at the University of Liverpool, created by the illness of Professor Sir Robert Boyce. Dr. Hay formerly held the office of medical tutor at the Royal Infirmary.

The Founder of the Children's Infirmary.

It has been suggested that the memory of the founder of the Children's Infirmary (the late Dr. Alfred Stephens) should be perpetuated by placing an inscription or other suitable memorial in the new building.

Jan. 22nd.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Statistics of the General Infirmary.

A TABULAR statement of the work done during the year ending Dec. 31st, 1906, shows an increase in most of the departments of the institution. The number of patients treated in the wards amounted to 7052, an increase of 287 as compared with the year 1905. The average number of in-patients was 365 and the fact that this number exceeds that for 1905 by only four is some indication of the fact that the pressure on the beds is considerable and that the infirmary is being worked

occasionally run dry. To lessen the frequency of such a contingency a small reservoir has been constructed and is placed on the top of a turret-like building. It is inside this building in immediate proximity to the water that the repugnant skinning of foetal lambs and calves takes place. One forgotten foetus was lying rotting outside the door at the moment of my visit. Inside I found a delicate-looking, fair young girl, perhaps 16 or 17 years old, wearing wooden clogs, dressed almost like a boy, and busy tearing the skins off a number of lambs that had been killed *in utero* by the slaughter of their mothers or that were stillborn. It seems to me that young women should not be employed on such work. This horrible proximity of girlhood with pre-natal death and destruction is most revolting. And just above was the reservoir of water which also should be kept pure.

It may be old-fashioned and unprogressive on my part, but I must confess that I was shocked at the work which women, and some quite young women, were allowed to do. One of the most repugnant sights, both on the south as well as the north side of the Seine, is the pig-bleeding room. At the Vaugirard slaughter-house, as well as at La Villette, women are employed to kill and to bleed the pigs. These animals are not thrown into boiling water, so that the bristles may be loosened by the scalding and then scraped off. As soon as they are killed and have bled sufficiently straw is piled around them and ignited. Thus the bristles are burnt off. This singeing process is often employed for bacon and not for pork. But it occasions a great deal of smoke and consequently the inside of the building where the pigs are killed is as black as a chimney, being covered throughout with a thick layer of soot. (See Fig. 2). This imparts a still more forbidding appearance to the whole place. The smell of burnt hair and flesh, the women collecting buckets full of blood, their blood bespattered clothes, their hands soaked and reeking with blood, the ear-piercing shrieks of the pigs, the steam from the hot blood, the sini-ter clatter of wooden clogs on the hard cemented floor, the callous if inevitable indifference to this daily massacre, all goes to make up a picture which is the very opposite of that which man is wont to associate with a reverent appreciation of the virtues of woman.

In the preparation of tripe, sheep and pigs' feet, &c., a large number of women are employed. At La Villette this is organised by private enterprise—that is to say, a syndicate of dealers in these by-products. They merely hire from the town of Paris and within the precincts of the abattoir buildings occupying 1200 square metres of land. In this restricted space they treat the edible by-products, tripe, calves' heads, &c., of some 2,000,000 animals per annum. This would not be possible but for the employment of very ingenious labour- and space-saving machinery. Nevertheless, there is much overcrowding which should not be allowed. Also a much stricter sanitary supervision is necessary. In the centre of a little hut where calves' and bullocks' feet were being prepared for culinary purposes there was an untrapped drain that gave forth a vile odour. This was a dark coachhouse-like structure in which nothing intended for human food should be permitted to enter. In another place I found that calves' heads were thrown on the floor; the dirt and grease aiding, they glided along and this was easier than carrying them from place to place. The skinning and then the packing of sheep's feet in bundles, like bundles of wood, were done in part by machinery and in part by the hand labour of women, who sat closely huddled together endeavouring to keep pace with the machinery. There was no systematic ventilation. The places were badly paved and in many instances the foul water could percolate into the subsoil. Above any amount of rafters preserved the dust and dirt of ages, occasionally allowing small particles thereof to fall on the food that accumulates below. Here was another excellent illustration of the fact so dramatically demonstrated at Chicago that, unless controlled by law, private enterprise makes no difference between what is to be eaten and other articles of industrial production. It is always a question of the economy of time, of space, and of labour—in other words, of the cheapness of production, without a single thought as to the safeguarding of the health of the workers and of the consumers.

Fortunately it is now fully recognised that the abattoir at La Villette no longer corresponds with modern requirements. Its days are numbered. Paris cannot afford to remain much longer behind Germany and Switzerland in regard to the sanitation of its meat-supply. The fact for instance, that men have to carry heavy portions of meat or carcasses on their backs is worthy only of the Middle Ages. At La

Villette there is but one really modern department. That is a large hall where the carcasses of the hogs are suspended and kept till the butchers fetch them away. Here there are the "omnibus" overhead rails so that the suspended carcasses are affixed to small wheels fitting to these rails and can be easily pushed along. Of course, these overhead rails are more needed for heavy horned cattle than for pigs, and should start from the slaughtering place. A carcass should be lifted up by pulleys and never carried. At La Villette, however, with the exception of the hogs, all are borne on the backs of the butchers, who, in such a dirty place, cannot possibly keep themselves clean. In the absence of mechanical appliances five men are employed to kill a bullock where in a slaughter-house with modern fittings three would suffice.

There should be no insurmountable financial difficulty in building new and model slaughter-houses for Paris. The abattoir of La Villette cost £1,200,000, which sum was repaid by yearly instalments, and the debt was liquidated long ago—namely, in the year 1887. At a congress of butchers held in Paris in 1894, the average cost and profit for the previous 13 years were given. Though there were somewhat ancient figures, I was led to infer that there had been no very material change since. If anything the profit must have increased, for there has been an increase in the number of animals slaughtered. The receipts were estimated as follows: 160,228,384 kilogrammes of meat at 2 per cent. on its sale price. This yielded an average annual income of 3,204,567 francs (£128,182). The rent paid by the dealers in tripe and other by products, and for the storage of meat, together with various small receipts, brought the total income up to 3,418,514 francs (£136,740). The working expenses were set down at an average of 699,283 francs, or £27,971, so that there remained a net annual profit of 2,719,232 francs, or £108,769. This is a sufficient income to guarantee a loan for building another and a better abattoir.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE spring term, which commenced last week, has started very favourably and the number of students at work is greater than in any previous term. By far the majority are studying applied sciences, but the numbers in the medical, arts, and commerce faculties are very satisfactory. In the medical faculty the work in the spring term is particularly heavy and no special lectures are to be delivered, but in the other faculties much additional work is to be done. The Social Study lectures have already recommenced and are to include Coöperation, Local Administration, and Public Health and Housing, which will be dealt with respectively by Professor A. Hley, Professor Masterman, and Dr. J. Robertson. On the 22nd of the month Professor Churton Collins recommenced his interpretative recitals, taking Shelley as his first subject. During the course of the term Mr. L. Doncaster will deliver a course of lectures on the Principles of Heredity and Variation in Animals and Plants, and on Wednesday evenings Mr. W. E. Collinge will lecture on Animal Pests of the Garden. There is therefore a very extensive series of lectures provided, which are open to all students of the University, either free or at a very small fee, and thus an excellent opportunity is afforded for them to step outside their own particular department and effectually to broaden their general outlook. In the Faculty of Commerce, which is pushing its way forward with no uncertain steps under Professor Ashley's able and energetic control, a new departure has been taken by the establishment of an advisory board of business men to coöperate with the professors in the Faculty. The step is a tentative one and is made with the object of gathering suggestions with regard to the training of students for business purposes from those who have practical experience of business demands, whilst at the same time it is hoped that the board will be able to bring the Faculty and its graduates to the notice of the business world.

The Housing Problem.

After a long discussion the city council decided to adopt the scheme of the housing committee for the disposal of the Bordesley Green site, to which attention was drawn in THE LANCET of Jan. 19th, p. 200. When

studies, and in the appointment of professorships, the adoption of which will modernise Trinity College and will give an immense stimulus to its energy and a vast extension to its intellectual outlook. 2. The commissioners gave their views as to how the vexed question of university education in Ireland is to be settled. Five different schemes to overcome the "religious difficulty" are discussed, and in the end the problem in Ireland was left as unsettled as is that of the English primary education question. The commissioners were unanimously of opinion that it was impossible to recommend any changes in the constitution of Trinity College which would make it acceptable to the Roman Catholic bishops, as the latter had assured them that they would not accept any scheme of mixed education in Trinity College and had disclaimed any desire to have changes made in the constitution of the College for their sakes. The *Times* in a leading article of Jan. 22nd remarks that the commission has left the main problem submitted very much as it was before. The problem is, of course, how to overcome the religious difficulty which obstructs the development of university education in Ireland. The commissioners, however, have with one dissentient recommended the establishment of a new college acceptable to Roman Catholics in Dublin. As regards the medical school, they recommend that effect should be given to the agreement embodied in the joint statement of the board of Trinity College and the President and Fellows of the Royal College of Physicians as submitted to the commission.

The Belfast Municipal Elections.

The remarkable result of the municipal elections held in Belfast on Jan. 15th, ending as they did in the return of all the candidates nominated by the Citizens' Association and pledged to economy, efficiency, and reform in civic administration, is an event unparalleled in our municipal history. Never before did such a large proportion of electors vote and the result has afforded the greatest satisfaction to all those who for the past year have pressed for a reform in the public health administration of the city. The uprising of the citizens was due in great measure to the controversy over the appointment of the medical officer of health. The action of the old corporation in this matter afforded the public an object-lesson in municipal tactics and the lesson has evidently been taken to heart. The Citizens' Association and the Ulster Medical Society have educated Belfast and have enabled the public to put on record their complete condemnation of a policy which, instead of grappling with the ominous condition of the health of the city, sought to minimise facts and to explain away statistics, while stigmatising the men who refused to shut their eyes and lips as slanderers. At the last meeting of the public health committee the following motion was carried:—

That a return be prepared and submitted by the medical superintendent officer of health of houses detrimental to the public health of the city or that are injurious to the health of the occupants, and also for maps showing the property already dealt with.

The public health committee is now awakened but the confidence of the citizens of Belfast has been shattered.

Belfast District Rural Council.

At a meeting of the Belfast district rural council held on Jan. 18th Mr. S. B. Coates submitted a report regarding different districts. 1. In the Whiteabbey district there has been an outbreak of typhoid fever caused by infected milk supplied by a dairy in the Larne union. 2. The Blackstaff river, which runs through the centre of Belfast, is being polluted by sewage contamination from several sources and its condition is becoming worse. The council decided to communicate with those causing this nuisance of the Blackstaff stream and also to adopt the Infectious Diseases (Notification) Act, 1877, and the Infectious Diseases (Prevention) Act, 1890, to come into operation on March 1st.

Epidemic Cerebro-spinal Meningitis in Belfast.

Those who wish to study fevers should come to Belfast, for now, in addition to almost every other type, we have an outbreak of that comparatively rare disease, cerebro-spinal meningitis. Five cases out of one family were sent to Pardysburn fever hospital where two have died. Unfortunately, one of the senior medical students of the Belfast Medical School sickened with symptoms of the disease on Jan. 13th and died on the 15th. Lumbar puncture revealed the presence of the specific diplococcus and in the fatal cases the organism was cultivated from the affected organs.

The Stoneyford Water-supply of Belfast.

At the quarterly meeting of the Lisburn rural council held on Jan. 19th Dr. R. Alexander of Knocknadona dispensary district and Dr. D. P. Gausson of Dunmurry reported very serious pollution of the Stoneyford catchment area (one of the sources of the Belfast water-supply) through surface water, liquid manure, &c., from farms in the catchment area getting into streams leading to the reservoir. It was resolved that the reports should be entered on the minutes and that copies should be sent to the authorities concerned in Belfast. There is no doubt that, if the water-supply at Stoneyford is to be above suspicion, the Belfast water commissioners must buy up all the farms in this catchment district.

Death of Mr. James C. McCleery, L.R.C.S. Irel.

Death removed on Jan. 19th, at his residence, Marsden Villa, Antrim-road, Belfast, the oldest member of the medical profession in Belfast, Mr. J. C. McCleery, at the advanced age of 83 years. Many years ago when he was a contemporary of the late Dr. James Smith, Dr. T. K. Wheeler, and Professor Cuning, Mr. McCleery, who lived then in the centre of the city of Belfast, had a very large and busy practice; about 20 years ago he retired from active work, but to the end he took the greatest interest in general affairs and preserved the genial spirit of his boyhood and youth. He was always pleasant and courteous, and was extremely popular with all who came in contact with him. His medical contemporaries had the highest opinion of his professional skill and ability. The utmost sympathy is felt with his widow and children.

Cork District Lunatic Asylum.

Dr. James J. Fitzgerald has been elected medical superintendent of the Cork District Asylum. The committee of management met on Jan. 14th, when Dr. Fitzgerald, formerly of Carlow, was unanimously elected. It will be remembered that Dr. J. P. Cashman was chosen some months ago by the casting vote of the chairman and that the Lord Lieutenant sent a letter stating that the appointment was illegal and that another election should take place. The result of the recent election is as above. The appointment is considered an important one in Cork and the election caused much interest.

Jan. 22nd.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Public Health.

THE excessive delay of the Direzione Generale di Statistica in publishing its reports prevents me from reviewing the public health, as a whole, for an earlier year than 1903. In that year the mean death-rate for the Italian kingdom was 22·25 per 1000. Taking the provinces first, the least healthy were those of Foggia and Bari, with a mortality of 30·7 for the former and 29·3 for the latter, while the most healthy were those of Treviso and Pisa, with a mean of 18 per 1000. Of the 69 capital cities of the provinces the maximum death-rate was reached at Catanzaro (Calabria), with a mortality of 32·4 per 1000; the minimum being that of Trapani (Sicily), with only 14·2. Of the great centres of population the healthiest were Turin, Rome, Genoa, Milan, and Palermo. While among the provinces those of the south showed the greatest mortality, among the cities there was no distinction between north and south as to salubrity—Bergamo, for example, in the Alta Italia, being little better than Catanzaro—a fact which shows how much leeway, in a sanitary sense, Italy has yet to make up. There is this grain of comfort, however, to be gathered from the report for 1903—namely, that among the healthiest provinces were Trapani, Grosseto, Rome, Cosenza, and Sassari, which but a few years ago were scourged with malaria, an endemic malady which all through Italy is gradually lessening in area and intensity. For 1903, as I have said, the mortality was 22·25 per 1000. In the next year it fell to 20·95. Unfortunately that advantage was not maintained and in 1905 it rose again to 21·73, although in that year small-pox had been virtually stamped out, malaria (thanks to the steadily progressive consumption of State-supplied quinine) had been much diminished, and other infective or contagious diseases had been in full defervescence. Italy, indeed, is a long way off the sanitary ideal contemplated by Agostino Bertani in his "Codice Igienico," and is

well up to its possible limits. The number of new patients admitted was 6760. Of these 1297 were medical, 3286 were surgical, exclusive of 804 accident cases, 722 and 301 were respectively eye cases and ear cases, and 350 were admitted into the gynaecological wards. The number of deaths was 489 and of these 148 occurred within 48 hours after admission. Calculating the death-rate on the remaining 341 it is found to be 4·8 per cent., a decrease of 0·21 per cent. In the out-patient department the number of new cases was 39,666. Of these 11,160 were medical, 4925 were surgical, 482 were gynaecological, 5102 were ophthalmic, and 2074 were aural. Casualties amounted to the large number of 11,254, an increase of 796 as compared with the previous year. Dental cases reached a total of 3558, skin cases and throat cases were respectively 147 and 873, while to the out-patient Finsen-lamp department and to the x-ray department there were admitted 27 and 63 new cases respectively. To the Ida and Robert Arthington Hospitals there were sent from the wards of the parent institution no less than 1247 cases, 341 in excess of the former year, and to other convalescent homes 249 patients were drafted. There is no doubt that the two special semi-convalescent homes above referred to, which are under the management of the infirmary board, are filling a very useful part in the work of the institution, providing accommodation as they do for patients who are not fit for being sent home or to the ordinary convalescent homes and who require skilled dressing or treatment. These two hospitals are under the care of the junior member of the honorary staff who, in so far as his infirmary duties are concerned, devotes all his time to the work. The quantity of stimulants—wine and spirits—consumed in the wards amounts this year to 109 gallons as compared with 85 gallons for 1905. The smaller figure works out to about one-tenth of an ounce per patient per day, so that the infirmary may fairly be regarded as an abstemious institution.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Scottish Students' Conference in Edinburgh.

THE annual conference between student representatives of the four Scottish universities was held in Edinburgh on Jan. 14th and 15th. Each university was represented by four members. On the second day of the conference various medical topics were discussed and voted upon. A motion to the effect that a lectureship on the History of Medicine should be instituted received an equal number of votes. The conference was also equally divided on a motion to the effect that class examinations should be taken in consideration in determining the results of degree examinations. The question of autonomy for the Scottish universities was also discussed but not voted upon; the opinion was expressed that if the universities obtained autonomy the student representative councils should be represented on the governing bodies. Principal Sir William Turner addressed the representatives on the training for public life. He pointed out that student life was a preparation for active life in the future; it was more than a mere living for the present. As educated men it was expected that they would hereafter take a part in the public life of the district of the country in which they lived and also in the public life of the State. Men of education, if they wanted to retain their proper position amongst their neighbours, must take an interest in public affairs. The interest consisted in being able to discuss the various questions affecting the life of the locality or of the State which might arise from time to time and of taking a broad view of them, not a mere narrow local view. He thought that such conferences gave a preparatory training for taking part in the discussion of public affairs.

Annual Report of the Chalmers' Hospital, Edinburgh.

During the year with which this report deals it is stated that the number of patients treated was 613, of whom 395 were in the public or free wards and 218 in the private or paying wards. The surgical cases numbered 348 and the medical 265. The daily average number of patients was 38 and 322 operations were performed. There was also a considerable number of out-patients treated. The ordinary expenditure amounted to £3435.

Death of Dr. Alexander Peddie.

On Jan. 19th Dr. Alexander Peddie died in Edinburgh at the age of 97 years. He graduated in 1835, was the oldest practitioner in Scotland, and was widely known as the friend of Dr. John Brown.¹

Bacteriological Diagnosis in Glasgow.

The health committee of Glasgow Corporation has issued a report on this subject which shows that during the year 1906 there were submitted for bacteriological diagnosis at the public health laboratory 1357 swabs from the throats of diphtheria patients, 663 tubes of blood from enteric fever patients, and the sputum of 1212 patients thought to be possibly suffering from pulmonary tuberculosis. According to the Glasgow Directory, there were 414 medical men in general practice within the city and 79·7 per cent. of these availed themselves of the laboratory for bacteriological diagnosis in these diseases. The total number of specimens submitted for examination during 1906 shows an increase of 457 over the previous year. The increase has been contributed from suspected cases of diphtheria and tuberculosis. During the past three years there has been a steady fall in the number of specimens from suspected cases of enteric fever and this is associated with a progressive diminution in the notification of this disease. Since the establishment of the laboratory it has frequently been found in connexion with outbreaks of diphtheria in households that bacteriological examination revealed the presence of the diphtheria bacillus in a percentage of those members of households who were apparently in good health. In March last this procedure was, as far as possible, adopted on systematic lines, and during the ten months 322 such "contacts" have been examined, with the result that the diphtheria bacillus was demonstrated in 34, representing 10·5 per cent. During the year 1032 rats—542 from the city and 490 from shipboard—were taken to the laboratory and examined for plague. No trace of this disease, however, was found in any of them.

Compliment to Professor J. G. McKendrick.

The business committee of Glasgow University General Council, of which Professor McKendrick was for some time convener, has resolved to initiate a movement to recognise in some way Professor McKendrick's long and distinguished connexion with the University and the city. It is intended that the movement shall be open to all who desire to testify their appreciation of Professor McKendrick and of his public and private services. A meeting will shortly be held to make arrangements, and meantime communications on the subject may be addressed to Mr. Archibald Craig, clerk of the general council.

New Joint Hospital at Duntocher.

The new joint hospital near Hardgate, Duntocher, was opened last week. The hospital occupies an ideal situation, the ground extending to fully three acres, upon which are six buildings in all. The administrative block, which has excellent accommodation, is in the centre of the site and to the east and west are the scarlet fever and the enteric fever pavilions respectively, the former having accommodation for 13 beds and the latter for nine beds. The hospital, which is built of red sandstone, will cost about £11,000. The population of the district to supply the hospital is about 20,000, but a little more accommodation has been provided than is likely to be required in the meantime.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Commission on the University of Dublin and Trinity College.

THE report of the members of the Royal Commission on the University of Dublin and Trinity College appeared on Jan. 22nd. The document divides itself into two sections. 1. The commissioners recommend a series of reforms in the internal administration of Trinity College, as, for instance, the reconstruction of the governing board, which will give all the Fellows (junior as well as senior) and professors a voice in its management and a radical reform in the system of election to fellowships, as well as a vital change in the constitution of the College council, in the arrangement of

¹ We hope to publish an obituary notice in an early issue.—ED. L.

recorded only 16 times. The patient, who was 50 years of age, had been suffering from enlargement of the thyroid body, and seven months previously to the operation the gland became acutely inflamed, in consequence, as was supposed, of a slight injury. A sinus leading into the left half of the thyroid body formed after some time, and, as it was very unpleasant and inconvenient to the patient and formed a cause of frequent recurrences of the inflammation, it was decided to operate. The operation proved a very difficult one on account of the existence of very extensive adhesions between the thyroid body and the neighbouring tissues, including the trachea, the submaxillary gland, and the large vessels. As regards the cause of the inflammation, the injury referred to could not with certainty be held responsible for it. A much more plausible hypothesis was the immigration of micro-organisms from the trachea by means of the lymphatics. The etiology of thyroiditis is not definitely known and the pathological anatomy is also not very clear. The 16 cases observed hitherto have not been examined methodically. In the present case there was found granulation tissue corresponding to the parenchymatous investment of the cystic tumour. In the inflammatory tissue there were many giant cells, containing colloid substance and needles of cholesterol. Similar findings have been reported in cases of acute thyroiditis without suppuration and in a case of Basedow's disease.

Jubilee of Professor Winternitz.

Professor Winternitz, who has just completed his seventieth year, will shortly celebrate his golden jubilee as a member of the medical profession. When he began medical study students of 16 or 17 years of age were admitted to the anatomical lectures and after a curriculum of three years could obtain their diploma. Professor Winternitz was the first among the Austrian medical teachers to call attention to the importance of hydropathic procedures in the treatment of disorders of the nervous system and metabolism, and numerous pupils of his clinic are now the directors of clinics for, or teachers of, hydropathy in Austria as well as in Germany.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Medical Events in 1906.

In Budapest the prominent event of the past year was the National Congress on Cancerous Diseases, the meetings of which were described in THE LANCET of Dec. 8th, 1906, p. 1626. The question of the third university in Hungary has been brought a step nearer to the realisation of the idea. Among topics of professional interest the most important feature of the year has been the movement for increasing the remuneration of the district and county medical officers. Their private fees are fixed by the State and these, together with their official salaries, are very low. The official salary of a district medical officer in the poorer parts of Erdély in Transylvania does not exceed £50 a year, and the fee for advice at the practitioner's house is fixed at 6d., while the fee for attendance at the patient's residence is 1s. There are districts where the private fees do not in a year amount to more than £40 or £50. These intolerable conditions will be altered now. The subject has come before Parliament and Count Andrássy, the Minister of the Interior, expects that the official salaries of county medical officers will be raised so as to range between a minimum of £100 and a maximum of £120.

The Prevention of Tuberculosis.

A sanatorium for tuberculosis will be erected in the near future for the workpeople of the State machine works in Algyó, a charming country place in Hungary, where fresh air, a fine river, and beautiful scenery supply the conditions suitable for a sanatorium. The initiator of this is Mr. Wekerle, the President of the Ministry, who when reading the mortality statistics of the men employed in the State machine works was struck by the high proportion (14 per cent.) of deaths caused by consumption.

The Spread of Venereal Diseases.

A census of venereal patients, be it made with ever so much care, is always incomplete, partly because many patients treat themselves and partly because of the great

number of irregular practitioners or quacks who compete with medical men in treating venereal diseases. Owing also to the long duration of venereal diseases patients often lose patience and go from one medical man to another, with the result that the same patient appears in the statistics several times. In the military statistics, however, all these difficulties of the enumeration are avoided and trustworthy data are obtained. According to the military statistics the prevalence of venereal diseases per 1000 men in the Austro-Hungarian army was as follows for the quinquennial periods from 1881 to 1900: 73.6 for the period 1881-86; 65.3 for the period 1886-91; 63.2 for the period 1891-94; 64.8 for the period 1894-95; and 61.0 for the period 1896-1900. The conclusion derived from these figures is that the incidence of syphilis is decreasing. An examination of the analogous statistics of other countries shows that the incidence of syphilis is highest in the English and Dutch armies. This is probably due to the large number of troops stationed in the colonies where venereal diseases are rife among the native population.

Jan. 19th.

Obituary.

THOMAS SAVAGE, M.D. ST. AND., F.R.C.S. ENG.

AMONG the numerous victims of the recent earthquake at Jamaica we greatly regret to find the name of Dr. Thomas Savage. Dr. Savage had made several trips to the West Indies and on this occasion sailed on Dec. 29th, 1906, with his nephew, Mr. O'Connell, and a lady friend of the family, Miss Hall, for the benefit of his health. The first report of the terrible event at Kingston caused considerable anxiety to his family; these fears for his safety were confirmed by the sad news of his death and of the death of those who accompanied him.

Dr. Savage was born at Wolverhampton in the year 1839. Destined at an early age for the medical profession he was apprenticed to Mr. Hadley of Ashted, Birmingham. He became a Member of the Royal College of Surgeons of England in 1860 and a Fellow in 1869; also in 1877 a Member of the Royal College of Physicians of London and M.D. of the University of St. Andrews in 1882. After his pupillage he was for two years house surgeon to the Eye Hospital, subsequently settling in general practice at Bordesley, a suburb of Birmingham. Dr. Savage was attached to Sydenham College—the then medical school—as lecturer on botany, and on the amalgamation of this institution with Queen's College he was appointed professor of comparative anatomy. In 1871 Dr. Savage was chosen as one of the four surgeons to the newly-founded Hospital for Women, where shortly after, on the resignation of one of the staff, he became senior surgeon, a position which he held until some ten years ago when he was appointed consulting surgeon. The circumstances attending his retirement were unfortunately due to the loss of one arm, disease in the elbow of which necessitated amputation. On his appointment to the Hospital for Women Dr. Savage devoted exceptional ability and energy to the work of that institution. He acquired considerable reputation as an operating surgeon and though the dominant power and personality of Mr. Lawson Tait on the same staff and in the same pursuit exercised much influence, Dr. Savage justly shared the fame which the hospital achieved in the impetus given to the position of gynaecology and in the extension of this knowledge to the profession. He subsequently became professor of midwifery at Queen's College, and on the merging of this school with the new University of Birmingham he was elected professor of midwifery. The chair was at this time divided between midwifery and gynaecology, and the latter was allotted to Mr. Lawson Tait. Professional success was attended with increased duties. Dr. Savage was appointed consulting surgeon to the Wolverhampton Hospital for Women, and to the Kidderminster Infirmary. He was at times also president of the British Gynaecological Society, of the Birmingham branch of the British Medical Association, and of the Medical Society in that city.

As a surgeon Dr. Savage was skilful, accurate, and careful. He enjoyed the confidence of his professional brethren as well as of a large circle of patients. He published the Ingleby lectures on Abdominal Section in 1881; also papers

not yet near the 15 per 1000 of other nations. Still she is on the progressive grade, "eppur si muove," and with her economic rehabilitation and the re-invigorated life of her academic and scientific institutions she must surely minimise the interval that divides her from the "Bertani goal" ere the twentieth century is many years older.

The Post-graduate Cliniques at Milan.

Jan. 11th was a medico-surgical festa at Milan, dedicated as it was to the opening of the Istituti Clinici di Perfezionamento the completion of which will ere long be an epoch-marking event in the Alta Italia. The Istituto Ostetrico-Ginecologico is already a *fait accompli*, the others will rapidly follow suit, while the post-graduate curriculum as a whole was appropriately initiated by an address on the History of Medicine by a master of the subject, Dr. Piero Giacosa, professor of materia medica in the University of Turin. That history will constitute of itself a special feature in the post-graduate curriculum, commencing with a survey of so-called "popular medicine," then settling down to the evolution of its first, rude pre-mature theories, contrasting the "dogmatic systems" characteristic of the peoples of the Far East with the "empirical systems" peculiar to those of the West. Then the course will take cognisance of medicine in its relation to philosophic speculation, to the religion, the customs, the commerce, and the social development of humanity. The influence of Christianity on theoretical and practical medicine will be duly considered, with full reference to the "monastic" and the "Saracenic" episodes in its history. Then, gradually working up to the epoch in which medicine assumes the form and substance of an independent science, the course will take in succession the various discoveries which have revolutionised theory and practice—by which time the student will be in a position to bring his critical faculties into play, so as to recognise the "traditional error" still nestling in current doctrine, and finally to reach the organic conception of health and its opposite made possible by "that magnificent ensemble of inductions which constitute the medicine and biology of to-day." The address in which this outline of the medico-historical course was adumbrated evoked repeated plaudits from the audience, professional and lay, which thronged the obstetrico-gynaecological pavilion and, in its published form, will find many to appreciate its conclusions, if not, indeed, to profit by the example it holds out to other "clinici di perfezionamento." The series of "courses" in post-graduate medicine will include one on the Physio-pathology, Theoretical and Clinical, of Social Maladies, by Dr. Edoardo Bonardi, professor of special pathology in the University of Pavia, in which cognisance will be taken of anæmia, rachitis, pellagra, malaria, typhoid fever, and the group of bacillary infections, alcoholism, uricæmia, diabetes, polysarcoma, and arterio-sclerosis. Another course, that of the epidemico-contagious diseases (scarlet fever, measles, small-pox, and diphtheria) will be given by Dr. Polverini, professor of "exotic medicine" in the Istituto di Studi Superiori in Florence; another on Clinical Orthopædia, by Dr. Galeazzi of the Institute for Rachitis in Milan; another on the Physio-pathology of Infective Diseases, by Dr. Belfanti, professor of bacteriology also in Milan; another on Traumatology, by Dr. Baldo Rossi; another on Ophthalmic Medicine and Surgery, by Dr. Ferri and Dr. Denti—to say nothing of the course on Clinical Obstetrics and Gynaecology, conducted by Porro's distinguished successor, the Senator Mangiagalli, and a fully equipped staff. Professor Mangiagalli, I may add, is the dean of this "new medical faculty," as the profession in Milan call it—a faculty which will reinforce itself from other schools (Turin, Florence, &c.) with eminent authorities in such subjects as Public Hygiene, Industrial and Commercial, and similar themes of universal interest.

Jan. 21st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Radio-activity of Water from Springs.

THE inclusion of radium amongst the curative agents of health resorts and medicinal waters has naturally led to a search for this substance in all the so-called "indifferent" thermal waters, the notion of which could not be explained hitherto. A large number of the Austrian health resorts have

now been found to possess a more or less considerable quantity of radio-active substances in their springs, and the deposits of the hot sulphur springs in Baden near Vienna, in Mehadia, and in Pistyan are useful as a source of radium. The most important of all these places, however, is Joachimsthal, where the pitchblende is found from which M. and Madame Curie obtained the first samples of radium. The mines there are the property of the Austrian Government which has ordered that the radium extracted from 10 tons of the pitchblende shall be delivered to the Vienna Academy of Sciences for distribution amongst hospitals, physical laboratories, and similar institutions. In Joachimsthal the water from the mines will be made use of for bathing purposes, and the establishment of a "radium curhaus" for certain ailments is contemplated by the local authorities. It may be mentioned that the Joachimsthal mine water has already been employed by medical men in cases of neurasthenia and anæmia, and of prostatic enlargement. The latter method has been already tried in Bad Gastein with satisfactory results, but it was found that the water must be used cautiously, as general symptoms (from the disintegration of the prostatic tissue) made their appearance in one case.

A Proposed Increase of Medical Fees.

At a meeting of the Union of Medical Clubs, held recently in Vienna, a resolution was adopted in which all practitioners were asked to raise their fees uniformly. The present social and financial conditions of medical practice are disheartening, for the cost of food, lodging, and other necessities of existence have increased so much that very many medical men are unable to maintain the position required by their profession. One of the latest burdens laid upon the practitioner is the raising of the amount payable for using the telephone, which has become dearer by 50 per cent. since the new year. The making of a charge for consultations by telephone had for a long time been in contemplation but the Aerztokammer (Medical Council), while not exactly discouraging the proposal, was not much in favour of it. Now it has left the question quite open for the profession to deal with and a unanimous decision will be undoubtedly arrived at in all the clubs. As regards the new fees the Aerztokammer is of opinion that the rate of payment for medical assistance is a matter for private arrangement and cannot be fixed for all uniformly. But a new tariff, a so-called minimal tariff, has been worked out, below which no practitioner should go unless the patient be really indigent. This tariff provides a fee of three kronen (2s. 6d.) for advice at the practitioner's house during consulting hours and a fee of from four to six kronen (from 3s. to 5s.) for attendance at the patient's residence, with an addition of 50 per cent. for night visits. For obstetrical or surgical work special fees are to be charged with a specified lower limit. Altogether the present scale of fees (which is, however, not binding for all practitioners in Vienna) has been increased by about 50 per cent. The public has been informed unofficially, but still very distinctly, through the newspapers, of the reasons for the increase of medical fees. Naturally the public try to pay as little as possible for medical attendance, but with the aid of organisation and unanimity the objections will be overcome.

Vital Statistics.

The last week of the year 1936 showed a few remarkable figures as regards the mortality and morbidity of Vienna. The sudden change of the weather and the great difference of temperature between morning and afternoon on Dec. 25th (in the morning -7°C . and in the afternoon $+6^{\circ}\text{C}$.) caused a rapid increase of the diseases of the upper air passage, and the wet warm weather had a harmful effect on the spread of the wet warm weather had a harmful effect on the spread of the infectious exanthematic fevers. The rate of mortality was 19.7 per 1000 and 743 deaths were reported in this week, of which three were due to typhoid fever, nine to measles, eight to scarlet fever, and eight to diphtheria. Pulmonary tuberculosis caused 110 deaths, and neoplasms caused 50 deaths. No case of variola has been seen in Vienna since the beginning of 1905; this long absence of the disease supplies an excellent argument against the antivaccination agitators. The number of infectious diseases which must be notified has been increased, trachoma and leprosy being added to the list, so that now there are 25 diseases classified as *anzeigepflichtig* (compulsorily notifiable).

A Case of Fistula after Thyroiditis.

Dr. Paul Albrecht has recently had occasion to operate upon a woman for a condition which hitherto has been

to share its splendid library and the large balance standing to its credit at the bank. Dr. H. R. Spencer acknowledged the toast on behalf of the Obstetrical Society of London and said that he looked upon the union of the Obstetrical and Gynaecological Societies as only a stage towards another union which would take place some day—namely, the union of the Royal College of Physicians of London with the Royal College of Surgeons of England, for it was those Colleges which ought to form the Royal Academy of Medicine in this country. Dr. Clement Godson proposed "The Guests," which was acknowledged by Director-General H. M. Ellis, R.N., and Surgeon-General Sir Thomas J. Gallwey, A.M.S. The last speech of the evening was from the chairman who paid a graceful tribute of thanks to Dr. H. Overy for his valuable services as honorary secretary.

APPRECIATION OF THE SERVICES OF A POOR-LAW MEDICAL OFFICER.—At a recent meeting of the Macclesfield board of guardians the chairman referred in felicitous terms to Mr. James B. Hughes, M.R.O.S., who for 40 years has been medical officer of the Macclesfield union infirmary. The chairman, after dealing with the remarkable improvement which had taken place with regard to the care of the patients during Mr. Hughes's connexion with the infirmary, said it was not often that Plato was quoted in a board of guardians, but Plato's remark that "No physician considers his own good in what he prescribes, but the good of the patient," particularly applied to Mr. Hughes, who had given of himself and of his best for the benefit of the poor, and he therefore asked the board to join in congratulating him upon having fulfilled 40 years' service. A vote of congratulation was unanimously carried.

WHITBY COTTAGE HOSPITAL AND THE MEDICAL STAFF.—The abuse of the out-patient department of the Whitby Cottage Hospital has induced the whole of the honorary medical staff to resign, and the matters in dispute have not been settled yet. As recorded in THE LANCET of Dec. 22nd, 1906, p. 1760, the medical men in a body walked out of the room in which the annual meeting was proceeding. Various endeavours have been made in the interval to come to some arrangement with the medical staff but the deadlock still continues. An influential committee, consisting of the Rev. Canon the Marquess of Normanby, Major R. Bell Torton, J.P., County Alderman R. O. Yeoman, J.P., Mr. E. H. Chapman (barrister), and the Rev. T. Rethmell (superintendent Wesleyan minister), has been appointed to confer with the medical men and to make whatever arrangements seem feasible with a view to carry on the hospital. A meeting was arranged with a committee from the members of the Whitby Medical Society, of which Dr. W. E. F. Tinley is the secretary, but the medical men declined to discuss the hospital committee's two suggested amendments unless their proposed alteration of a rule affecting the out-patient department was accepted, viz.:—

That the out-patient department shall be limited to those who had been in-patients of the hospital and require further attendance, and to those who had not been in-patients, but who are recommended by a medical man, except in urgent accident cases.

The conference of the hospital sub-committee with the representative of the medical staff (Dr. G. B. Mitchell) was abortive and the deadlock continues, but it is hoped that a satisfactory *modus vivendi* will soon be attained.

LEPROSY IN BRITISH GUIANA.—Mr. G. D. Bayley, acting assistant Government Secretary of British Guiana, in his report in the Blue Book of the colony for the year 1905-06, mentions that the system of segregation of lepers continues to be enforced so far as possible. The total number of inmates in the Leper Asylum on March 31st, 1906, was 420. The deaths during the year had numbered 71 and the discharges 20. The indoor and outdoor work was carried on as usual. The net cost of the institution for the year was £4609, exclusive of the medical officer's salary. The colonial legislature has enacted an ordinance making further provision for the care of lepers and for the taking of precautions against the spread of leprosy which unfortunately is greatly on the increase in the colony. The ordinance provides that lepers wandering abroad, and others who cannot be properly isolated in their own homes, shall be sent to the leper asylum. Provision is made for householders and employers of labour reporting cases of leprosy to a medical officer.

Certain trades, in which articles of food or clothes have to be handled, are prohibited to lepers and precautions are authorised for preventing the landing of lepers in the colony. Power is also given to declare part of the leper asylum to be a prison, in which lepers sentenced to imprisonment may be confined, so as to avoid the risk of lepers carrying contagion to an ordinary prison. A similar provision is made for lunatic lepers so as to prevent the risk of contagion to persons in the ordinary lunatic asylums.

CENTRAL LONDON OPHTHALMIC HOSPITAL (GRAY'S INN-ROAD).—The new pathological, bacteriological, and x ray laboratories of this hospital, which were long felt to be a necessity, are now fully equipped for carrying on the work of the hospital. It is further proposed that they shall be open to students for research work in connexion with the pathology of the eye. Classes with lantern demonstrations have been arranged to begin in February. Special attention will be paid to the histology of the eye and to the more recent work on opsonins. The hospital affords ample material for the proper carrying on of research work in these subjects.

MEDICAL BARRISTERS.—Two medical men are to be "called" this Hilary term—namely, by Gray's Inn, Hedley Coward Bartlett, L.R.C.P. Lond., M.R.C.S. Eng., of Saffron Walden, Essex; and by the Middle Temple, Heinrich Oppenheimer, LL.B., M.D. Heidelb., M.R.C.P. Lond., M.R.C.S. Eng., of Hampstead.

BOOKS, ETC., RECEIVED.

SMITH, ELDER, AND CO., 15, Waterloo-place, London, S.W.

Climatotherapy and Balneotherapy. The Climates and Mineral Water Health Resorts (Spas) of Europe and North Africa. Including the General Principles of Climatotherapy and Balneotherapy, and Hints as to the Employment of Various Physical and Dietetic Methods. Being a third edition of "The Mineral Waters and Health Resorts of Europe," much enlarged in respect to Medical Climatology. By Sir Hermann Weber, M.D., F.R.C.P., Consulting Physician to the German Hospital, London, the Royal National Hospital for Consumption, Ventnor, and the Mount Vernon Hospital for Diseases of the Chest, Hampstead; Hon. President of the British Balneological and Climatological Society; and F. Parkes Weber, M.D., F.R.C.P., Physician to the German Hospital, London, and to the Mount Vernon Hospital for Diseases of the Chest, Hampstead. Physical Chemistry in the Service of Medicine. Seven Addresses. By Dr. Wolfgang Pauli, Privat-docent in Internal Medicine at the University of Vienna. Authorized translation by Dr. Martin H.

on Oophorectomy and on the Treatment of Uterine Myoma, and, in 1891, the presidential address to the branch entitled "Some Aspects of the Present State of Gynecology." Nor did his activity cease on his retirement from the work of his profession. After his illness he took a house in the country at Knowle in Warwickshire where he still continued to maintain an interest in many charitable and useful kinds of work. There he was appointed a magistrate for the county; he became also a county councillor, in which capacity he rendered valuable work as a member of the sanitary and education committee of the county council. His judgment was sound, his knowledge was widely varied, and his tastes were cultured. Added to a high sense of duty and steadfastness of purpose, he possessed settled principles of fairness and impartiality. His many qualities of character made him much respected as a citizen and valued with deep regard as a friend.

Dr. Savage married in 1864 Miss Gosling of Richmond, Surrey. He leaves his widow, one son (Dr. Smallwood Savage), and three daughters. One son, Dr. Arthur Savage, died a few years since on the threshold of a career full of bright prospects of success.

WALTER JOHN SYKES, M.D. EDIN., D.P.H. CAMB.,
F.I.C.

THE public analysts of this country have lost a great friend and a valued contributor to applied science by the death of Dr. Walter John Sykes, who was editor of the *Analyst* for the past 15 years. Dr. Sykes died suddenly at his residence in East Grinstead on Dec. 16th last. He was born at Wakefield in 1842 and was educated at the local grammar school. He chose medicine for his profession and graduated as M.D. in 1866 at the University of Edinburgh. He was house surgeon at Clayton Hospital, Wakefield, in which town he ultimately established a general medical practice, which after a few years he gave up and then went to Heckmondwike. He was subsequently appointed medical officer of health of the borough of Portsmouth, succeeding Dr. George Turner, now chief medical officer of the Orange River Colony. He gave up this appointment, which included that of public analyst, in 1886 and decided to take up the study of chemistry, chiefly from the analytical point of view. He devoted special attention to the chemistry of brewing and published several important papers on the subject and finally wrote a book of admitted practical value entitled "The Principles and Practice of Brewing," the second edition of which has only recently passed through the press. The current number of the *Analyst* contains an appreciative and feeling notice of Dr. Sykes's career and attractive personality by Mr. Otto Hehner and an excellent portrait.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. A. E. Macdonald, formerly professor of mental diseases and of forensic medicine at the University and Bellevue Hospital, New York. Dr. W. J. Herdman, professor of neurology and psychiatry in the Ann Arbor University, Michigan. Dr. Dron, one of the senior surgeons in Lyons.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the Congregation on Jan 17th the following degrees were conferred:—

M.D.—G. S. Keeling, Caius.
M.C.—E. C. Hughes, Clare.
M.B. and B.C.—O. May, St. John's; and P. R. Parkinson, Caius.
B.C.—G. W. Goodhart, Trinity; P. P. Laidlaw, St. John's; J. W. Linnell, St. John's; D. G. Pearson, Pembroke; N. Wilson, Pembroke; G. F. S. Bailey, Caius; J. H. Iles, Caius; D. K. Nutman, Jesus; F. P. Young, Christ's; F. A. Barker, Emmanuel; T. S. Hele, Emmanuel; S. L. Walker, Sidney Sussex; and W. H. R. Sutton, Downing.

UNIVERSITY OF OXFORD.—The following are the degree days in the present term:—Saturday, Feb. 16th, at 2.30 p.m.; and Thursday, March 14th, at 10 a.m.—The days fixed for the commencement of the B.M. examinations in 1907 are Thursday, June 20th, and Thursday, Dec. 5th. Names must be entered not later than 10.30 a.m. on Tuesday, June 4th, and Tuesday, Nov. 19th, respectively.—The day fixed for receiving names for the examination for the degree of Master of Surgery is June 7th.—

The examination for the Radcliffe Travelling Fellowship, already announced, will commence on Tuesday, Feb. 26th. The names are to be sent in to the Regius Professor of Medicine on or before Saturday, Feb. 9th. Full details are given in the *University Gazette* of Jan. 18th, 1907.—Examinations for scholarships in natural science are announced as follows: March 12th, Keble College; March 18th, Merton College and New College.—The Vice-Chancellor has appointed the Right Honourable Lord Curzon of Kedleston, M.A., Hon. D.O.L., of All Souls' College, G.O.S.I., G.C.I.E., F.R.S., who was appointed last year but was prevented from delivering the lecture, to be the Romanes Lecturer for 1907.—Mr. C. M. Burrell of the Merchant Taylors' School has been elected to a scholarship in natural science in University College.

MEDICAL MEN AND COMMISSIONS.—At the Bournemouth county court on Jan. 18th, before Judge Philbrick, K.C., Dr. G. E. J. Crallan sought, as secretary of the Association of Medical Men Receiving Resident Patients, to recover from Dr. T. C. Fisher, of Torquay, £6 11s. 3d. being 5 per cent. commission on the sum of £131 5s., the amount of fees received up to the end of 1906 from a patient alleged to have been introduced to the defendant through the medium of the association. In giving judgment, his honour said: "An association of professional gentlemen which by its rules stipulated for the payment of commission on sums received in respect of patients was somewhat of a novelty. It was not his duty to act as censor, but he was by no means convinced that such associations, or such stipulations, as these deserved encouragement, and as he did not believe that the patient was obtained through the association he gave judgment for defendant."

LITERARY INTELLIGENCE.—Among the additions to the "World's Classics" to be published immediately by the Oxford University Press are the evergreen works of Professor Oliver Wendell Holmes "The Poet" and "The Professor at the Breakfast Table." Scott's "Lives of the Novelists," with introduction by Mr. Austin Dobson; Thackeray's "Pendennis," with introduction by Mr. Edmund Gosse; and "Sheridan's Plays," with introduction by Mr. Joseph Knight, are also announced in the same series.—Two monographs of interest to aural surgeons are shortly to be published by Messrs. J. and A. Churchill. One is entitled "Some Points in the Surgical Anatomy of the Temporal Bone from Birth to Adult Life," by Mr. Arthur H. Obeath, F.R.C.S. Eng., aural surgeon to King's College Hospital. The work is illustrated with reproductions of photographs of specimens. The other work is upon "The Labyrinth of Animals," and contains 30 reproductions of stereoscopic photographs. The author is Mr. A. A. Gray, M.D. Glasg., F.R.S. Edin., aural surgeon to the Victoria Infirmary, Glasgow.

BRITISH GYNÆCOLOGICAL SOCIETY.—Mr. F. Bowreman Jessett, President of the society, took the chair at the annual dinner, which was held at the Monaco Restaurant, Regent-street, London, on Jan. 17th. Dr. F. H. Champneys, in submitting the toast of "The British Gynecological Society," said in regard to the amalgamation scheme of the medical societies that there were those who prophesied that new societies would be formed outside the main body as had happened abroad. But as far as related to the section which would be formed by the union of the Obstetrical and Gynecological Societies the amalgamation of those bodies would render it impossible for any successful opposition to be set up outside the section. The toast was replied to by the chairman. Mr. W. D. Spanton proposed the toast of "The Royal College of Physicians of London and the Royal College of Surgeons of England," which was acknowledged by Dr. Amand Routh, who, speaking on behalf of the Royal College of Physicians, declared that the work of the profession and from that point advantage and dignity of the profession and of the society of view it did not lose sight of gynecology. Mr. Henry Morris, President of the Royal College of Surgeons, who also replied to the toast, said that it must be admitted by all that the introduction of gynecology into surgery was a great advantage, for it without doubt led to the better understanding of the better treatment of a great number of maladies. "The Obstetrical Society of London" was the next toast, which was proposed by Dr. H. Macnaughton-Jones, who took the opportunity to bestow warm praise on that society for throwing itself in with the common lot in the amalgamation scheme of the societies, thereby enabling others

to share its splendid library and the large balance standing to its credit at the bank. Dr. H. R. Spencer acknowledged the toast on behalf of the Obstetrical Society of London and said that he looked upon the union of the Obstetrical and Gynaecological Societies as only a stage towards another union which would take place some day—namely, the union of the Royal College of Physicians of London with the Royal College of Surgeons of England, for it was those Colleges which ought to form the Royal Academy of Medicine in this country. Dr. Clement Godson proposed "The Guests," which was acknowledged by Director-General H. M. Ellis, R.N., and Surgeon-General Sir Thomas J. Gallwey, A.M.S. The last speech of the evening was from the chairman who paid a graceful tribute of thanks to Dr. H. Overy for his valuable services as honorary secretary.

APPRECIATION OF THE SERVICES OF A POOR-LAW MEDICAL OFFICER.—At a recent meeting of the Macclesfield board of guardians the chairman referred in felicitous terms to Mr. James B. Hughes, M.R.C.S., who for 40 years has been medical officer of the Macclesfield union infirmary. The chairman, after dealing with the remarkable improvement which had taken place with regard to the care of the patients during Mr. Hughes's connexion with the infirmary, said it was not often that Plato was quoted in a board of guardians, but Plato's remark that "No physician considers his own good in what he prescribes, but the good of the patient," particularly applied to Mr. Hughes, who had given of himself and of his best for the benefit of the poor, and he therefore asked the board to join in congratulating him upon having fulfilled 40 years' service. A vote of congratulation was unanimously carried.

WHITBY COTTAGE HOSPITAL AND THE MEDICAL STAFF.—The abuse of the out-patient department of the Whitby Cottage Hospital has induced the whole of the honorary medical staff to resign, and the matters in dispute have not been settled yet. As recorded in THE LANCET of Dec. 22nd, 1906, p. 1760, the medical men in a body walked out of the room in which the annual meeting was proceeding. Various endeavours have been made in the interval to come to some arrangement with the medical staff but the deadlock still continues. An influential committee, consisting of the Rev. Canon the Marquess of Normanby, Major R. Bell Turtton, J.P., County Alderman R. O. Yeoman, J.P., Mr. E. H. Chapman (barrister), and the Rev. T. Rathmell (superintendent Wesleyan minister), has been appointed to confer with the medical men and to make whatever arrangements seem feasible with a view to carry on the hospital. A meeting was arranged with a committee from the members of the Whitby Medical Society, of which Dr. W. E. F. Tinley is the secretary, but the medical men declined to discuss the hospital committee's two suggested amendments unless their proposed alteration of a rule affecting the out-patient department was accepted, viz.:—

That the out-patient department shall be limited to those who had been in-patients of the hospital and require further attendance, and to those who had not been in-patients, but who are recommended by a medical man, except in urgent accident cases.

The conference of the hospital sub-committee with the representative of the medical staff (Dr. G. B. Mitchell) was abortive and the deadlock continues, but it is hoped that a satisfactory *modus vivendi* will soon be attained.

LEPROSY IN BRITISH GUIANA.—Mr. G. D. Bayley, acting assistant Government Secretary of British Guiana, in his report in the Blue Book of the colony for the year 1905-06, mentions that the system of segregation of lepers continues to be enforced so far as possible. The total number of inmates in the Leper Asylum on March 31st, 1906, was 420. The deaths during the year had numbered 71 and the discharges 20. The indoor and outdoor work was carried on as usual. The net cost of the institution for the year was £4609, exclusive of the medical officer's salary. The colonial legislature has enacted an ordinance making further provision for the care of lepers and for the taking of precautions against the spread of leprosy which unfortunately is greatly on the increase in the colony. The ordinance provides that lepers wandering abroad, and others who cannot be properly isolated in their own homes, shall be sent to the leper asylum. It is made for householders and employers of labouring cases of leprosy to a medical officer.

Certain trades, in which articles of food or clothes have to be handled, are prohibited to lepers and precautions are authorised for preventing the landing of lepers in the colony. Power is also given to declare part of the leper asylum to be a prison, in which lepers sentenced to imprisonment may be confined, so as to avoid the risk of lepers carrying contagion to an ordinary prison. A similar provision is made for lunatic lepers so as to prevent the risk of contagion to persons in the ordinary lunatic asylums.

CENTRAL LONDON OPHTHALMIC HOSPITAL (GRAY'S INN-ROAD).—The new pathological, bacteriological, and x ray laboratories of this hospital, which were long felt to be a necessity, are now fully equipped for carrying on the work of the hospital. It is further proposed that they shall be open to students for research work in connexion with the pathology of the eye. Classes with lantern demonstrations have been arranged to begin in February. Special attention will be paid to the histology of the eye and to the more recent work on opsonins. The hospital affords ample material for the proper carrying on of research work in these subjects.

MEDICAL BARRISTERS.—Two medical men are to be "called" this Hilary term—namely, by Gray's Inn, Hedley Coward Bartlett, L.R.O.P. Lond., M.R.C.S. Eng., of Saffron Walden, Essex; and by the Middle Temple, Heinrich Oppenheimer, LL.B., M.D. Heidelb., M.R.C.P. Lond., M.R.C.S. Eng., of Hampstead.

BOOKS, ETC., RECEIVED.

SMITH, ELDER, AND CO., 15, Waterloo-place, London, S.W.

Climatotherapy and Balneotherapy. The Climates and Mineral Water Health Resorts (Spas) of Europe and North Africa. Including the General Principles of Climatotherapy and Balneotherapy, and Hints as to the Employment of Various Physical and Dietetic Methods. Being a third edition of "The Mineral Waters and Health Resorts of Europe," much enlarged in respect to Medical Climatology. By Sir Hermann Weber, M.D., F.R.C.P., Consulting Physician to the German Hospital, London, the Royal National Hospital for Consumption, Ventnor, and the Mount Vernon Hospital for Diseases of the Chest, Hampstead; Hon. President of the British Balneological and Climatological Society; and F. Parkes Weber, M.D., F.R.C.P., Physician to the German Hospital, London, and to the Mount Vernon Hospital for Diseases of the Chest, Hampstead. Member of the British Balneological and Climatological Society. Edited by F. Parkes Weber. Price 15s. net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BIRT, A. C., M.R.C.S., L.R.O.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Wantage District of the county of Berks.

CULROSS, J., M.B., O.M. Glasg., has been re-appointed Honorary Medical Officer to the Newton Abbot Hospital.

DOUTY, EDWARD H., M.A., M.D., M.O. Cantab., F.R.C.S., M.R.C.P., M.D. Paris, &c., has been appointed Surgeon to the Queen Victoria Memorial Hospital, Nice.

GRIMBLEY, R. H., M.R.C.S., L.S.A., has been re-appointed Honorary Surgeon to the Newton Abbot Hospital.

HAYDON, E., M.B., O.M. Glasg., has been re-appointed Honorary Surgeon to the Newton Abbot Hospital.

HOSFORD, J. STROUD, F.R.C.S. Edin., has been appointed Honorary Assistant Surgeon to the Royal Eye Hospital, Southwark.

MARKS, URIAH, M.R.C.S., L.R.O.P. Lond., has been appointed House Physician at the Worcester Infirmary.

POLLARD, G. S., M.R.C.S., L.R.O.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Midmore Norton District of the county of Somerset.

ROSS, S. J., M.D. Vict., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Bedford District of the county of Bedford.

SHAW, W. F., M.D. Vict., has been re-appointed Resident Surgical Officer to the St. Mary's Hospitals, Manchester.

WATKIN, ARTHUR CHRISTOPHER, L.R.O.P. Lond., M.R.C.S., has been appointed House Surgeon at the Aberystwyth Infirmary.

YOUNG, J. STIRLING, M.B., Ch.B. Vict., has been appointed Fourth House Surgeon at St. Mary's Hospitals, Manchester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BANGOR, CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House Surgeon. Salary £20 per annum, with board, washing, and lodging.

BARROW-IN-FURNESS, NORTH LONDON HOSPITAL.—House Surgeon. Salary £100 per annum, with board and lodgings.

BEADFORD HOSPITAL AND WORKHOUSE.—Resident Assistant Medical Officer, unmarried. Salary £100, with rations, apartments, and washing.

BRISTOL DISPENSARY.—Medical Officer.

BRISTOL ROYAL INFIRMARY.—Resident Junior House Surgeon. Also Resident Casualty Officer. Both for six months. Salaries at rate of £50 per annum, with board, lodging, and washing. Also Resident Obstetric Officer. Salary £75 per annum, with board, lodging, and washing.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Surgeon for six months, renewable. Salary at rate of £60 per annum, with board, washing, and apartments.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road.—Registrar for in patients. Honorarium 20 guineas a year.

CHETSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Registrar. Honorarium £40 per annum.

CITY OF LONDON LYING-IN HOSPITAL, City-road, E.C.—District Surgeon for Upper Holloway.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry.

GLOUCESTER GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £30 per annum, with board, residence, and washing.

HAMPSTEAD GENERAL HOSPITAL.—Resident Medical Officer for eight months. Salary at rate of £50 per annum, with board and residence.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Assistant House Surgeon for six months. Honorarium £20, with residence, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician also Assistant Casualty Medical Officer, both unmarried. Salary in each case 25 guineas for eight months, with board and residence.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians for six months. Honorarium of £25. KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum and board.

KING EDWARD VII. SANATORIUM, Midhurst Sussex.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and attendance.

LEEDS, HOSPITAL FOR WOMEN AND CHILDREN.—Resident Clinical Assistant.

LIVERPOOL STANLEY HOSPITAL.—Honorary Physician. Also House Surgeon. Salary £50 per annum, with board, residence, and washing.

LONDON COUNTY COUNCIL.—Lecturers to Evening Classes for Midwives and Maternity Nurses. Fee £22s. a lesson.

LONDON LOCK HOSPITAL.—House Surgeon to the Female Hospital. Salary £20 per annum, with board, lodging, and laundry. Also Surgeon to Out-patients.

MANCHESTER, ANCOATS HOSPITAL.—Resident House Physician. Salary £20 per annum, with board &c.

MENSTON, NEAR LEEDS, WEST RIDING ASYLUM.—Second Assistant Medical Officer. Salary £200, rising to £250, with board and apartments. Also Fourth Assistant Medical Officer. Salary £150, rising to £180, with board and apartments.

NEWCASTLE-UPON-TYNE AND NORTHUMBERLAND SANATORIUM FOR CONSUMPTION, Barrasford-on-Tyne.—Resident Medical Officer. Salary £120 per annum rising to £220, with board and laundry.

NEWPORT BOROUGH ASYLUM, Caerleon (Mon.).—Assistant Medical Officer, unmarried. Salary £170 per annum, with board, apartments, and attendance.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Honorary Anaesthetist.

PADDINGTON INFIRMARY.—Second Assistant to the Medical Superintendent for six months. Salary at rate of £72 per annum, with board, lodging, and washing.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Assistant House Surgeon for six months, renewable. Salary £50, with board, residence, and washing.

REETH UNION DISTRICT AND WORKHOUSE, Yorkshire.—Medical Officer. Salary £37 10s.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Resident Medical Officer for six months. Salary at rate of £120 per annum, with apartments, board, and washing.

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL.—Honorary Assistant Anaesthetist.

ROYAL PHILIPICO DISPENSARY, 104, Buckingham Palace-road, S.W.—Visiting Medical Officer.

SHEFFIELD, UNIVERSITY OF SHEFFIELD.—Chair of Pathology.

STROUD GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100 a year, with board and apartments.

TUNBRIDGE WELLS GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, &c.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Two Assistant Resident Medical Officers, unmarried. Salary £81, with board and lodging.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Honorary Surgeon.

Births, Marriages, and Deaths.

BIRTHS.

EDELSTEIN.—On Jan. 15th, at Brixton-road, S.W., the wife of Ernest A. Edelstein, M.B., M.A., of a son.
HODGSON.—On Jan. 18th, at Leyburn, Mitcham-lane, S.E., the wife of Charles Hodgson, L.R.O.P. Lond., M.R.C.S. Eng. of a son.
KEMPTHORNE.—On Jan. 9th, at Lahore Cantonments, India, the wife of Gerard Ainslie Kemplthorne, B.A. M.C., of a daughter.
RAMFORD.—On Jan. 19th, at Croxley Green, Herts, the wife of Alan C. Ramford, M.R.C.S., L.R.O.P., of a son.
RYALL.—On Jan. 19th, at 77, Harley-street, W., to Mr. and Mrs. Canny Ryall—a son.
TIBBITS.—On Jan. 18th, at Jury-street, Warwick, the wife of Hubert Tibbitts, M.B., of a daughter.

MARRIAGES.

AVELING-SHIMWELL.—On Jan. 23rd, at St. Wilfrid's Church, Northenden, by the Rev. Thomas Shimwell, M.A. (brother of the bride), assisted by the Rev. Lowrie Hamilton, M.A., Rector of the Parish, and the Rev. John Brunster, Vicar of Gately, Leslie Baldwin Aveling, B.A., M.B., B.C., of Park Lane House, Royston, to Dorothy, second daughter of William James Shimwell, of Gately, Cheshire.
SIMON-OLARKE.—On the 17th, at St. George's, Hanover-square, by the Rev. Canon Bristol, M.A., of Southwark Cathedral, assisted by the Rev. Daven Jones, D.A., Vicar of Kidwelly, and the Rev. David Anderson, M.A., Rector, Captain Harold Simon, R.A.M.C., third son of Thomas Simon of Blackheath, to Kate Litton, eldest daughter of Ernest Clarke, M.D., F.R.C.S., of Chandos-street, Cavendish-square.
THOMPSON-CLARKE.—On Jan. 15th, at St. Peter's Church, Morley, by the Rev. H. T. Robinson, B.A., assisted by the Rev. F. Eyles, M.A., the Rev. Andrew Douglas, M.B., Ch.B., Edin., fourth son of Alexander Thompson, Esq., Barmal, Wigtonshire, N.B., to Amy Winifred Thompson, second daughter of J. O. Clarke, M.R.C.S. and L.S.A., of Bank House, Morley, Yorks.—At home, Comberton House, Halesowen Feb. 17th and 18th.

DEATH.

PEDDIE.—On Jan. 19th, at Rutland-street, Edinburgh, from pneumonia, Alexander Peddie, M.D., F.R.C.P.E., &c., in his 97th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A GREAT ESTATE, ITS AGENT, AND THE MEDICAL PROFESSION.

WE refused recently to publish an advertisement sent to us by Mr. Henry Whitcomb in behalf of the Petworth Park Friendly Society, of which society he is secretary. We did this because we do not insert advertisements of vacancies for medical officers to such societies until we have seen the rules of the society, or until we have had an opportunity of learning the position enjoyed by the previous holder of the appointment if circumstances point to the advisability of obtaining the information. Mr. Whitcomb asked us to state our reasons "in common fairness to the committee and the president of the society, Lord Leconfield," whose estate, he informs us, "is one of the largest private estates in the South of England." We hasten to explain the situation quite clearly to Lord Leconfield and the committee. Firstly, we have never seen the rules of the Petworth Park Friendly Society. Mr. Whitcomb failed to send them to us, and a later communication from Mr. Herbert E. Watson, the chairman of the society, also failed to inclose them, though alluding to them as an inclosure. Secondly, the remuneration of the medical officer to the Petworth Friendly Society works out on the present terms at under 3s. per head per annum, for which sum he will be expected to attend in all directions of Petworth within a radius of seven miles, confinements and surgical cases included. We want Lord Leconfield to grasp the fact that this is extremely bad pay, and that we do not desire to help the society over which he presides in any intention which that society may have to continue to give such terms.

The decision that we were unable to insert the advertisement was strongly confirmed by the following letter which was later received by our manager:—

Jan. 22nd, 1907.

DEAR SIR,—The secretary of the Petworth Park Friendly Society has shown me the correspondence he has had with your paper in reference to this society. The Right Honourable Lord Leconfield is president of this society and as it appears to be one of your rules for advertisements that you should have a copy of the society's rules, I herewith enclose you one, but I gather from your letter that the real reason for not inserting the society's advertisement was that you had had an intimation from Petworth in reference to it. I quite anticipated that this was the case and therefore urged the secretary to write his letter of the 19th January.

For over 50 years this society has retained the services of a resident medical man in Petworth and increased the payment for attendance some ten or 12 years ago, so that for the last ten years it has averaged £75. As chairman, I called a meeting of the members to consider the resignation of their medical officer and put this question to them: "Are you prepared to pay a higher contribution for medical attendance?" They unanimously said, "No." I then put it to them: "Would you like to advertise for another doctor?" This they again unanimously answered in the affirmative.

There are two other doctors practising in this place and, before coming to the conclusion to advertise, the members offered these doctors the post at the same price as their late officer, but they declined it. The society therefore had no other alternative but to advertise for a doctor.

I must say that it is somewhat hard that a body of labouring men should thus be apparently boycotted by the doctors in the place and not even allowed to make their wants known through the ordinary channels of the medical profession. I most certainly shall, unless you are prepared to reconsider your determination not to insert this advertisement, make known as publicly as possible the tyranny of the medical profession, for I can call it by no other name. We hear of trades unionism amongst the working classes, but I do not think from my present experience of the medical profession that it is confined to one class.

Yours faithfully,

HERBERT E. WATSON,
Agent to the Lord Leconfield.

P.S.—There being three doctors in the place I think you are bound to give the name of your informant, otherwise you will be doing them an injustice.—H. E. W.

The agent to the Lord Leconfield has a few things to learn, as well as how to write a polite and coherent letter. Responsible journalists are not to be bounced into accepting advertisements because the "one of the largest private estates in the South of England" makes threats of letting the public know his disapproval of them if any other course is pursued. The demeanour assumed by Mr. Watson may prove efficacious when collecting the rents of the said l.p.c., &c., but off Lord Leconfield's soil he will find it futile. The fact that the medical men in the locality refused the post—we thank Mr. Watson for the information—sufficiently proves what the figures we have given indicate. The terms of the Petworth Park Friendly Society are unfair to their medical officer.

DENTISTRY BY LIMITED COMPANY.

WE have received the following letter which does not bear any address upon it. We do not know if the names which it contains are genuine or fictitious:—

Jany. 11th, 1907.

To the Editor of THE LANCET, London.

DEAR SIR,—An answer to the following queries in your next issue will oblige.

I carry on the business of chemist and druggist, &c., as a limited company and employ as manager of my extensive dental practice a gentleman to whom patients are referred for treatment under the style of *Doctor Henderson*. This gentleman also uses the initials D.D.S. after his name on cards, notepaper &c., and is advertised as, and calls himself, a Doctor of Dental Surgery. (Walter James Henderson, D.D.S., F.S.Sc. (London).) As he has never been to America it is illegal for him to use this title without having a diploma for it? simply as an advertisement for the good of the business, and can proceedings be taken against him as I know it is impossible to prosecute me for referring to him as such, being a limited company?

I suppose there can be no objection to him exhibiting a diploma such as the Society of Science, London, describing him as a D.D.S., as a harmless form of advertisement, and it is impossible to take any proceedings.

Although he holds no degree, &c., is there anything to prevent him taking apprentices to learn dentistry?

Your kind reply in an early issue will oblige, as I shall feel sure your replies will be legally correct, and I wish to keep within the law, and avoid losing money. Please reply to,

G. COVERDALE, LTD.

The Dentists Act of 1878 was passed for the purpose of protecting the public from irregular and unqualified dental practitioners. It is no part of the duty of a journal devoted to medical sciences to point out to correspondents the methods by which the legal provisions of the Act can be circumvented and irregular practice indulged in without incurring such penalties as are at present attached to it. We publish this letter because it is a good sample of the tactics to which the public is likely to become a prey owing to the unsatisfactory conditions of the Medical, Dental, and also the Pharmacy Acts.

LOATHSOME BED-STUFFING.

To the Editors of THE LANCET.

SIRS,—My attention has been called to a letter appearing in your paper on "Loathsome Bed-stuffing," and I am pleased to note that Mr. W. T. Ellery has had the courage to speak up to his conviction. Would that other manufacturers did the same.

Writing from an outside point of view, I do not think the manufacturers are altogether to blame, but I consider the makers of the beds and mattresses are at fault; they buy a common class shoddy—in fact, made from what Mr. Ellery describes to be "the commonest and dirtiest rags obtainable"; they stuff the bedding with and label it with such words as "sanitary" or "purified." Such words as these are misleading and beguile the public into buying a cheap article, leading them to think it is perfectly hygienic.

I am, Sirs, yours faithfully,

Jan. 19th, 1907.

SANTAS.

THE TREATMENT OF "NEURALGIA."

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent who in your issue of Jan. 5th asked for suggestions as to the treatment of a case of brachial neuralgia, I would point out that certain cases of a similar condition have been reported as being relieved by the application of the cataplasms kaolin of the United States Pharmacopoeia. This, according to the sixth edition of Shoemaker's "Materia Medica and Therapeutics," contains kaolin with glycerine as an excipient and boric acid, methyl salicylate, and oil of peppermint. It should be applied warm and confined with a bandage. I am, Sirs, yours faithfully,

Jan. 19th, 1907.

M.R.C.S.

HUMMING AND SINGING.

At a recent meeting of the Bedford board of guardians the question of accepting the resignation of the head nurse at the workhouse infirmary came up. We cannot gather from the report what led to the nurse sending in her resignation, but it is clear that there was no serious cause. In the course of the discussion, however, Mr. Pettit, a guardian, is reported as saying: "The matron won't have the nurse singing or humming about her work. Now, I maintain that if any one is sick or dull and has a nurse about always humming and with a cheerful countenance it is better than medicine (hear, hear), and for any one to say another shall not sing or hum is to take the sunshine out of one's life, while to reprimand her about that is very, very, very—well, I'll leave off there" (laughter).

Now with all due respect to Mr. Pettit we quite agree that a cheerful nurse is much better than a gloomy one, but we cannot hold that when one is sick and dull a nurse who sings and hums is desirable. Anything more aggravating we cannot conceive. Mr. Pettit must have derived his ideas from that class of novel which describes the joy of hearing a young girl's voice about the house.

singing blithely over her work. A well-known physician, now dead, gave a description of the proper way to prepare a salad, which we recommend to Mr. Pettit's attention. "The salad ought to be dressed by one of the daughters of the house, after she herself was dressed for dinner, singing, if not with voice, with her clean cool fingers, sharp silver knife, and wooden spoon." The Italics are our own, and so we say that the cheerful nurse should sing "not with voice."

JERRY-BUILT DWELLINGS.

At a recent inquest in the Battersea coroner's court a bricklayer, whose little child had perished in the fire which burnt down the house in which he lived, said: "The place was so jerry built that when my fires have not been alight smoke has come through from the next door neighbour's." A fireman who found the little girl's body gave evidence that the lath and plaster was only one and a quarter inches thick and that the flooring was five-eighths of an inch in thickness. Further evidence showed that the house was built about 30 or 40 years ago and was of a stamp common in the locality. Presumably modern building Acts would prevent such a structure being put up at the present time, but the risk of accidental fire taking place in houses which have stood for 40 years is not one which can be established so as to enable them to be closed. It is at least a matter for congratulation that the efforts made to protect the poor against the jerry-builder are bearing some fruit in the shape of new houses of a better type than the old ones which they are gradually replacing.

Liverpool.—The strength of the solution mentioned by our correspondent is correct but he omits to mention what "indicator" he employs. If the soda solution contained carbonate the results would be misleading if an indicator sensitive to CO₂ were used. To be quite certain the best plan is to check the soda solution by running in decinormal acid, using the same indicator as in the experiment.

R. W. J.—We regret the delay in answering our correspondent's question, but it was necessary that we should make an inquiry. We understand that no discourtesy whatever was intended. The hospital in question was almost certainly following a rule which exists in other hospitals that such certificates should be filled up by someone appointed by the institution.

M.D.—We agree that the advertisements are disgraceful and have made reference to them. We understand that there is difficulty in the police taking action in the matter.

Kemel.—We have not under our hand the references which our correspondent asks for. We will, however, attempt to obtain them.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopaedic (4 P.M.), St. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (3 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (3 P.M.), St. Mark's (2.30 P.M.).

TUESDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (2.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central square (9.30 A.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (2 P.M.), Ophthalmic, 215 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (30th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Free (2 P.M.), Royal Orthopaedic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.).

THURSDAY (31st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West (1.30 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), London (2 P.M.), Gt. Northern Central (Throat, 9.30 A.M.), Samaritan (2.30 P.M.), Metropolitan (2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopaedic (9.30 A.M.), Royal Free (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.), Tottenham (Gynaecological, 2.30 P.M.).

FRIDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopaedic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Dental, 2 P.M.), Tottenham (2.30 P.M.).

SATURDAY (2nd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (28th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M.: Discussion on Some Points in the Diagnosis and Treatment of Laryngeal Cancer (introduced by Sir Felix Semon, C.V.O.).

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—7 P.M.: Council Meeting. 8 P.M.: Casual Communications.—Dr. W. L. H. Duckworth: A Note on the Dentition of Some New Guinea Skulls.—Mr. H. B. Gardner: Continuous Nasal Administration of Nitrous Oxide with Oxygen. Paper.—Mr. P. Turner: Tumours of the Superior Maxilla (illustrated with microscopic sections and specimens).

WEDNESDAY (30th).—BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—5.30 P.M.: Discussion on the Influence of Climate upon Gout, Rheumatism, and Rheumatoid Arthritis (introduced by Dr. G. W. Buckley, Buxton). Dr. J. Groves (Isle of Wight), Dr. H. Cumming (Torquay), Dr. P. Lewis (Folkestone), and others hope to take part in the discussion.

THURSDAY (31st).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-square, W.).—8 P.M.: Card Specimens. 8.30 P.M.: Papers.—Mr. S. Snell: (1) A Case of Tubercle of the Eyeball in which the Opsonic Index was regularly taken; (2) A Family Tree of Nyctalopia.—Mr. A. Lawson: Two Cases of Streptococcal Infection of the Conjunctiva.—Mr. G. B. James: Some Notes on Stereoscopic Vision.

FRIDAY (1st).—SOCIETY OF ANAESTHETISTS (20, Hanover-square, W.).—8.30 P.M.: Paper.—Dr. L. Guthrie: Poisonous After-effects of Chloroform and of Ether.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (28th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Dr. G. Little: Clinique. (Skin.) 5.15 P.M.: Lecture.—Dr. A. J. Whiting: Traumatic Neurosis.

POST-GRADUATE COLLEGE (West London Hospital, Hammermith-road, W.).—12 noon: Pathological Demonstration.—Dr. G. C. Low. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays Operations. Mr. Dunn: Diseases of the Eye. 5 P.M.: Clinical Lecture.—Dr. Saunders.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 A.M.: Clinique.—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Cliniques: Medical Out-patient (Dr. Whilpham), Throat, Nose, and Ear (Mr. Carson); X Ray Demonstration (Dr. Pirie).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Sir D. Duckworth: Medicine. 3.15 P.M.: Mr. W. Turner: Surgery. 4 P.M.: Dr. St. Clair Thomson: Diseases of the Throat, Nose, and Ear. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat. Special Lecture.—Dr. St. Clair Thomson: Nasal Suppuration.

TUESDAY (29th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Dr. B. Cautley: Clinique. (Medical.) 5.15 P.M.: Lecture.—Mr. A. H. Cheate: The Surgical Anatomy of the Temporal Bone, its Bearings on Suppuration (with lantern slides).

POST-GRADUATE COLLEGE (West London Hospital, Hammermith-road, W.).—10 A.M.: Dr. Moullin: Gynaecological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: X Rays. Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Lecture.—Dr. Low: Ankylostomiasis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—10.30 A.M.: Clinique.—Medical Out-patient (Dr. Auld). 2.30 P.M.: Surgical Operations (Mr. Carson); Cliniques: Gynaecological Out-patient (Dr. Giles), Surgical Out-patient (Mr. Edmunds). 4.30 P.M.: Lecture Demonstration.—Mr. Cooper: Electro-diagnosis.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. E. T. Hewlett: Medicine. 3.15 P.M.: Mr. Carless: Surgery. 4 P.M.: Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen's square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture.—Dr. Tooth, O.M.G.: Cerebral Palates of Infancy.

CHARING CROSS HOSPITAL.—4 P.M.: Demonstration.—Dr. Murray: (Medical) (Post-Graduate Course).

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.).—3 P.M.: Prof. A. O. Seward: Survivals from the Past in the Plant World. (Lecture 1.)

WEDNESDAY (30th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Mr. P. L. Daniel: Clinique. (Surgical.) 5.15 P.M.: Lecture.—Dr. G. L. Jones: Cervical Ribs and Muscular Atrophy of the hands (with lantern slides).

POST-GRADUATE COLLEGE (West London Hospital, Hammermith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. Dr. Robinson: Diseases of Women. 5 P.M.: Lecture of Stricture of the Urethra.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 P.M.: Cliniques.—Dermatological (Dr. Meacham), Ophthalmological (Mr. Brooks), Medical Out-patient (Dr. Whippleham).
LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. R. Wells: Medicine. 3.30 P.M.: Mr. Cargill: Ophthalmology. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 11 A.M.: Eye. Special Lecture: Mr. Cargill: Iritis.
CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.O.).—5 P.M.: Demonstration.—Mr. Stuart-Low: Middle Ear and Labyrinth.

THURSDAY (31st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.O.).—4 P.M.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M.: Lecture.—Mr. L. Mummery: Rectal Hemorrhage, its Causation and Treatment.
POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M.: Lecture.—Mr. Baldwin: Practical Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 P.M.: Gynecological Operations (Dr. Giles). Cliniques.—Medical (Dr. Whitting), Surgical Out-patient (Mr. Carson). 3 P.M.: Clinique.—Medical In-patient (Dr. Chappel). 4.30 P.M.: Lecture.—Dr. Macdonald: The Pathology of the Pneumonia.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. G. Rankin: Medicine. 3.15 P.M.: Sir W. Bennett: Surgery. 4 P.M.: Dr. H. Cooper: Radiography. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat. Special Lecture.—Dr. Rankin: Angina Pectoris.

ST. JOE'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.O.).—6 P.M.: Chesterfield Lecture.—Dr. M. Dockrell: Treatment (Constitutional and Local in all its Forms).

CHANDLER CROSS HOSPITAL.—4 P.M.: Mr. Boyd: Demonstration (Surgical). (Post-Graduate Course.)

HOSPITAL FOR SICK CHILDREN (St. Ormond-street, W.O.).—4 P.M.: Lecture.—Mr. Fairbank: Hip Disease.

FRIDAY (1st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.O.).—4 P.M.: Dr. D. Grant: Clinique. (Ear.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moulin: Gynecological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. 3.30 P.M.: X Rays. Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Lecture.—Mr. C. William: X Rays, Diagnosis and Treatment (with lantern slides).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 A.M.: Clinique.—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds). Cliniques.—Medical Out-patient (Dr. Auld), Ophthalmological (Mr. Brooks). 3 P.M.: Clinique.—Medical In-patient (Dr. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. R. Bradford: Medicine. 3.15 P.M.: Mr. McGavin: Surgery. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queens-square, Bloomsbury, W.O.).—3.30 P.M.: Clinical Lecture.—Dr. Ferrier: Cases from the Wards.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.).—9 P.M.: Sir A. E. Wright: The Methods of Combating the Bacteria of Disease in the Interior of the Organism.

SATURDAY (2nd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. Dr. Robinson: Diseases of Women.
LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1906, which was completed with the issue of Dec. 29th, were given in THE LANCET of Jan. 5th, 1907.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1906 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.O., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.	TO THE COLONIES AND ABROAD.
One Year £1 12 6	One Year £1 14 8
Six Months 0 16 3	Six Months 0 17 4
Three Months 0 8 2	Three Months 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.O.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

A Post-Graduate Lecture

CONCERNING

PAIN IN THE GROIN,

Delivered at the London Clinical School of Medicine (Seamen's Hospital), on Jan. 24th, 1907.

By SIR WILLIAM BENNETT, K.C.V.O.,
F.R.C.S. ENG.,

CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL; SENIOR SURGEON
TO THE SEAMEN'S HOSPITAL, ETC.

GENTLEMEN,—Several years ago, by one of those coincidences which are not rare in practice, I was consulted within 48 hours by three patients solely on account of pain in the fold of the groin, without swelling, tenderness, or any other objective symptom within the immediate neighbourhood. Pain in the groin was the trouble complained of and pain in the groin was the only thing from which relief was sought. The cases proved interesting; they had already been treated by others without benefit and they served the useful purpose of leading me to investigate rather more carefully than, I believe, I had hitherto done cases in which the only cause for seeking advice was pain in the groin. I have now got together sufficient memoranda of cases of the same type which have since come under my notice and it is with this series that I propose to deal to-day. The cases had the following points in common. 1. Pain continuous or intermittent in the fold of the groin without swelling, tenderness, or any other sign of lesion near the seat of pain. 2. An impression on the part of the patient that the cause of the pain was above or below the groin, as the case may have been, without being able to locate it. On analysis, however, in a considerable number of the cases this impression was very vague and the patients were obliged to admit that they could not tell whether the incidence of the pain was from above or from below. The primary impression, however, proved, as a rule, to be correct. In the majority of the cases movements of the hip-joint, however free, whether passive or voluntary, had no effect upon the pain, but in some the pain was either produced or increased by extreme flexion or by forced extension. In no case was there any restriction in the normal movements of the hip-joint so far as the patient was aware. The table gives a general idea of the cases so far as diagnosis was practicable:—

54 Cases in which Pain in the Fold of the Groin was the only Symptom complained of. (Recent injuries are not included.)

Incidence of pain apparently from above.	Cases.	Incidence of pain apparently from below.	Cases.
Prolapse of the ovary ...	1	Small omental femoral hernia ...	1
Omentalumbilical hernia ...	1	Small femoral hernial sac ...	1
Tumour of the pelvis ...	1	Obturator hernia ...	1
Malignant disease of the rectum ...	1	Saphenous varix ...	4
Stone in the bladder ...	1	Osteoma of the tibia ...	1
Stone in the ureter ...	3	Femoral atheroma ...	2

The right groin was concerned more frequently than the left but I have no record of the exact proportion. The large majority of cases were in males; those in women did not patients who first attracted my stated, been variously treated

without benefit; in one the cause of the pain was found to be an irritated, completely retained (abdominal) testis, in another there was a small omental femoral hernia, and in a third a stone in the ureter accounted for the solitary symptom. Although in a few of the cases the diagnosis was not absolutely certain, in the large majority it was undeniably accurate. In the course of the investigation of the cases it was clear that pain localised in a curiously limited area could be produced by conditions sometimes so remote that I confess I should have previously been sceptical as to the possibility of the causation.

A point of some interest, having regard to subsequent experience, was elicited whilst investigating the cases—viz., that in a minority only of the patients who had previously been under treatment had any careful examination of the gluteal and perineal region or of the lower limb below the middle of the thigh been made, although in all cases abdominal examination seemed to have been thorough—a capital example of the predominance of abdominal considerations in the minds of practitioners at the present time. A considerable number of the patients had undergone “cures” at continental and other watering places frequently upon the advice of friends and on the chance apparently of gout or rheumatism being at the bottom of their troubles. It is obviously in the time at our disposal as impossible as it is unnecessary to deal with all the cases tabulated. In some the relation of the groin pain to its causative disease is obvious; of the remainder, it is only possible to call your attention to the most interesting.

CASES IN WHICH THE INCIDENCE OF THE PAIN SEEMED TO THE PATIENT TO BE FROM ABOVE.

Small umbilical hernia.—A man, 33 years old, suffered from continual discomfort in the right groin, which sometimes during defecation became acute, and was always intensified when the arms were extended about the head and in hyper-extension of the lower limbs. Nothing abnormal could be felt at the seat of pain and a careful search in all directions failed to detect anything unnatural excepting a minute omental protrusion by the side of the umbilicus. No connexion could at the time of this discovery be made out between the little hernia and the pain, but subsequently the patient became convinced in his own mind that the two were associated and the protruding lump was removed. No further pain in the groin was felt.

The case of malignant disease of the rectum was very instructive as no suspicion of its existence had previously arisen. The patient was a man, about 50 years of age, who complained merely of a continual aching pain in the right groin, which was always to some extent increased in the standing position; there was no tenderness or other sign of disease; the patient seemed in perfect health. A question about the action of his bowels led him to say that everything was natural but that occasionally he had noticed that the groin pain became rather acute during defecation. A rectal examination revealed as high as the finger tip could reach a small hard nodule the touching of which increased the pain in the groin.

Stone of the bladder.—The patient was a man advanced in years, singularly hale and well preserved. The attacks of pain in the groin were acute and intermittent, the intervals between the attacks varying from hours to days; the left groin was concerned as a rule, but sometimes the right was affected; the attacks generally occurred upon rising from bed in the morning, and at times were so acute that he had to lie down again until they passed off. Nothing abnormal could be discovered. The urine was normal and the vesical functions were natural. Finally, an attack of pain of the usual kind was followed by acute retention of urine from impaction of a calculus in the urethra. This was passed spontaneously before surgical aid was forthcoming. No further attacks of the pain occurred. It is possible, of course, that the stone had previously been lying in the ureter, but the bladder seemed to be its more likely situation.

Stone in the ureter.—In these cases the left ureter was concerned in two, and the right in one. All the stones were diagnosed and located by the x rays. Three stones were present in one case; in the others the stone was single. The only symptoms complained of were continual pain and discomfort in the corresponding groin. Nothing abnormal could be seen or felt until the x rays showed the stones. There were no urinary symptoms of any kind. In two cases the stones were small and were finally passed, after which all pain disappeared. The third case was the following.

A man about 40 years old had suffered for years from a more

or less constant pain in the right groin; it was never acute and rarely entirely absent. As a rule, it was worse in the morning on leaving his bed and again towards evening. The patient thought it was a little increased when the bladder was full but he was rather vague on the subject. No objective signs of lesion could be made out. The bladder and bowel functions were normal excepting a rather hesitating act of micturition which he said was natural to him. The x rays showed a stone of considerable size at the extreme vesical end of the ureter. Removal of this by suprapubic cystotomy entirely relieved the groin pain. Apart from the question now under discussion these cases are particularly useful in showing the value of the x rays in vague pain and in demonstrating how greatly the actual symptoms sometimes caused by stone in the ureter differ from those described in books.

Stricture of the urethra.—In neither of these cases was stricture suspected. Pain in the groin was the only trouble. The most striking case was as follows. A man, aged 30 years, had suffered from continual aching pain in both groins for nearly two years. He had suffered from slight gonorrhoea when very young which was cured without complications. His symptoms had been regarded as rheumatic, the usual remedies having been used without benefit. In passing a sound in order to eliminate the remote possibility of a vesical cause for the pain a stricture was found in the usual situation which admitted a No. 7 bougie with slight difficulty. During the passage of the bougie through the stricture the pain in the groins became acute, especially on the left side. This, of course, gave the clue to the cause of the pain. Full dilatation of the stricture was followed by complete disappearance of the groin pain which had shown no sign of reappearance a year later. On passing a bougie through the stricture after an interval of three months from the time of full dilatation the pain in the left groin was temporarily reproduced, subsiding in a few hours.

In the cases of *retained testicles* the cause of the pain was self-evident when the condition of the testicles had been ascertained. It was, however, a remarkable fact that in two of the cases in which both testicles were in the abdomen and entirely impalpable, the scrotum being rudimentary, neither patient (both were grown men, one being married) had the least idea that he was the subject of any abnormality, a misapprehension which might have been accounted for by the abundantly developed penis which was present in each instance.

The *tumour of the pelvis* was discovered by the x rays. The pain was of the type under notice, but was somewhat increased by hyper-extension of the thigh. Nothing abnormal was perceptible to the touch. The growth was somewhat pedunculated and situated at the junction of the horizontal ramus of the pubic bone with the ilium on the right side. When discovered it had the appearance of an osteoma but subsequent events showed that it was sarcomatous.

The case in which a *Meckel's diverticulum* accounted for the pain was very interesting. The symptom which led to advice being sought was merely pain in the right groin which at times was acute and was always exaggerated by exercise. Nothing abnormal could be detected by the x rays or by any other means. Upon subsequent careful questioning it was, however, elicited that when the pain was excessive the patient invariably felt "blown up" and the abdomen became hard, walking being then only possible in a rather bent attitude. That this statement was correct was verified by observation. Constipation habitually existed but seemed to have no relation to the pain. (The only other case in the series in which somewhat similar symptoms occurred is the next following.) I thought in the present instance that some adhesions or, perhaps, a small omental hernia in the inguinal canal might have caused the trouble. The pain increased so much that radical measures became necessary with the result that a Meckel's diverticulum was found adherent by its apex and providing all the conditions for potential "strangulation by band"; it was divided and the symptom ceased.

The symptom again in the two cases of *irreducible incomplete inguinal hernia* was merely pain in the fold of the groin; in one, occurring in a man, no other symptom could be detected on palpation, but coughing caused a distinct increase in the pain, as did also lying on the opposite side of the body; when the pain was at its worst some abdominal distension was said to occur but it was not verified by observation. The symptom became so distressing that the patient begged for something to be done which might give relief. The lower end of the inguinal canal was therefore

internal ring was found to be blocked by a mass which proved to be an omental hernia. In the woman the symptom was less severe. An examination made whilst the patient was lying down revealed nothing abnormal but in the standing position there was sufficient fulness over the region of the canal to show that abnormality existed. She did not think it worth while to submit to operation.

The *spinal abscess* was interesting because it was one of those unassociated with spinal pain, tenderness, or rigidity. The only symptom complained of was pain in the groin. The movements of the hip were quite free but forcible extension of the thigh not only increased the pain in the groin but caused pain over the area supplied by the anterior crural nerve about the front aspect of the thigh. These symptoms, with much exaggerated knee-jerks, made the case pretty certainly one of very early psoas abscess, a diagnosis which was subsequently confirmed.

Two cases were quite *undiagnosable* so far as I am concerned, one being a very remarkable one. A healthy man approaching 50 years of age contracted what was at first thought to be influenza, the effects of which passed off in three or four days. Then, after an interval of 48 hours, rigors and high fever were followed by acute cystitis of a hemorrhagic type. The necessary catheterisation was followed by acute epididymitis. Ultimately, after some weeks, he made what seemed to be a perfect recovery, but upon getting about his affairs as usual for three weeks or thereabouts he began to suffer from a deep-seated feeling of pain in the fold of the groin on the opposite side to that of the testicle which had been involved. There was no tenderness or other abnormality, only this perpetual feeling of deep pain. The bladder and rectum were quite normal; the seminal vesicles were not tender or large. This pain persisted for about 18 months without much alteration, there having been during that time three or four nocturnal emissions which consisted apparently of little more than blood in considerable amount. At the end of the time mentioned the pain began to increase without any other abnormal development until it became intolerable; nothing gave relief. Finally, the patient being in the country decided to come to London to see a surgeon and left his house in acute pain to drive to the station, a distance of four miles; before half the distance had been traversed the pain suddenly disappeared, leaving neither tenderness nor discomfort of any kind, and I understand that although five months have elapsed there has been no sign of recurrence. I am bound to admit that I do not know what the lesion was nor do I in any way understand the case.

CASES IN WHICH THE INCIDENCE OF THE PAIN SEEMED TO BE FROM BELOW.

The two cases in which the pain in the groin appeared to be due to some abnormal condition in the crural canal occurred in women. In the first, in which the fault proved to be a very small irreducible omental tag, no symptom other than pain in the groin fold could be elicited, but this was increased by coughing although no unnatural impulse was noticeable, and by forcible extension of the thigh. In the other case the pain was not increased by coughing or hyper-extension, but in the erect position there was a very slight fulness over the saphenial end of the canal which was nonexistent on the opposite side. It was so slight that in ordinary circumstances it would probably have escaped notice, but being at the time much on the alert in cases of this kind it was sufficiently pronounced. The condition was found to be a minute empty hernial sac, having a very small accumulation of fluid in the sac as the day went on.

In another case I diagnosed an *obturator hernia* but no opportunity of verifying the diagnosis was offered. The patient was a woman who complained of pain immediately below Poupart's ligament occurring only occasionally, but when it occurred it was very acute. Nothing abnormal could be seen or felt nor was there any tenderness. On careful inquiry it transpired that coughing increased the pain and on occasions there had been a feeling of nausea which nearly ended in vomiting; moreover, if the pain continued for some hours it seemed to extend down the inner side of the thigh to the knee and it always disappeared suddenly, complete comfort immediately following. It had hitherto been thought to be a neurotic trouble, but I have no doubt that this impression was at all events wrong.

In the cases of groin pain in which marked *saphenous varix* was present the cause was obvious, i

thing being that the cause did not seem to have been previously recognised, probably, I fancy, because, judging from what the patients said, the only examination made had been in the recumbent position when, of course, the varices were not obtrusive. In the standing position they were very obvious. Three of the cases were operated upon with complete relief.

The *osteoma of the tibia* was a remarkable case. A man, aged 25 years, who came over from South Africa during the Boer War, complained of frequent attacks of extremely acute pain in the left groin rather to the inner side. The attacks appeared to occur only when the limb was being flexed whilst it was rotated outwards as, for an example, when he crossed the limb over the opposite thigh; on a few occasions it had occurred during some action, such as kicking; once it had been produced in a most acute form by accidentally knocking the leg against the step of a cab. In the groin there was absolutely nothing abnormal to be detected; there was no "click" or other sign of mechanical trouble in the hip-joint. He described the pain as giving him an impression of being "hit from below." Whilst examining the lower part of the leg for a possible, though unlikely, cause he cried out that I had started the pain, which was obvious from the expression of suffering in his face; the pain rapidly passed off and was reproduced by manipulation of the same part. Ultimately I found a small hard tumour which the x rays showed to be very spiky in shape (*osteoma*?) springing from the inner side of the tibia about four inches from its lower end; pressure upon this in certain positions of the limb always produced the pain. I suppose some filament of the saphenous nerve must have been involved. Arrangements were made for the removal of the offending lump, but something led to the patient postponing operation and I never saw him again.

In connexion with the above case the following is worthy of mention, although the pain was located over the knee, because it not only shows how remote the cause of a local pain may be, but how a well-recognised condition may be mimicked in a most unlikely way. A well-known London medical man had for some time suffered from sudden attacks of pain which he attributed to recurrent displacement of a semilunar cartilage in the knee. The attacks seized him suddenly, as a rule, whilst turning quickly round in walking or when walking upon uneven or sloping ground. So acute were the attacks that they "stopped" him for a few minutes and then rapidly disappeared. No effusion into the joint had been noticed and no positive mechanical "locking" had happened. Such arrest in the movements of the joint as had occurred seemed to be due solely to the acuteness of the pain. So crippling had the symptoms become that he consulted me with a view to consider the desirability of having the defective cartilage removed. Although the history related would fairly fit certain cases of knee-joint derangement I was rather sceptical about the existence of this because the knee appeared to be altogether normal, showing none of the signs of laxity or "wobbling" which, so far as I know, is always present in cases of recurrent attacks of derangement. Some further inquiries elicited the fact that the attacks of pain occurred only whilst boots or shoes were being worn—rather a suggestive fact seeing the frequency with which the attacks occurred. Following upon this an examination of the foot revealed a sensitive corn, pressure upon which produced an attack of pain like those described. Modification of boot pressure resulted in a disappearance of the deceptive symptoms of derangement of the knee-joint. This is an admirable case to demonstrate the soundness of what I am very fond of teaching—viz., that the true attitude of the diagnostician is that of a "detective," which is essentially one of suspicion even when things seem obvious. Had I been less wary and had I failed to appreciate the bearing of the evidence of the boot, which was, of course, the clue to the case, it is not unlikely that I might have seriously considered the question of exploration of the knee-joint. It would be exceedingly interesting if it were possible to ascertain the number of joints and other cavities which have been explored in search of faults of which they are entirely innocent.

A further excellent example of a remote cause for pain in the groin is afforded by the case of a *melanotic mole* in the sole of the foot. The patient, a woman of an admitted highly strung and neurotic type, complained of repeated attacks of acute pain in the groin whilst walking which occurred with distressing frequency. No explanation could be advanced for the oncoming of these attacks beyond the

belief of the patient that she was gouty which had led her to seek relief at watering places without success. As to the reality of the pain there was no doubt it had none of the characteristics of "neurotic" pain as commonly met with. It always occurred when stepping in a certain way but she had no knowledge of any tender spot on the foot. The pain, however, which was felt upon the "front of the hip" could be avoided by walking as much as possible on the outer side of the foot. Upon examination there was found at the inner side of the sole a flat black mole of the size of a threepenny-piece, deep pressure upon which produced a pain in the groin similar to that sometimes felt in walking. Removal of the mole was followed by entire disappearance of the pain complained of.

Of a similar type was the case in which pain in the groin arose in connexion with *flat foot*. The patient was a boy 14 years old, and although the existence of the valgus was known it had received no attention as it had, so far as those concerned could tell, given rise to no inconvenience. The provision of an appropriate brace and the use of rational exercise rapidly improved the condition of the foot and were followed by the disappearance of the pain in the groin.

Of the two cases of *old fracture of the tibia*, one was the result of a gun-shot wound, the other being an oblique fracture below the middle of the tibia, the upper end of the lower fragment projecting inwards in a very exaggerated way. The pain in the groin in each case occurred when rapid flexion of the knee or hip took place; the same movement slowly and carefully performed caused no pain. In neither case did the patient connect the pain in any way with the old injury. The long saphenous nerve was, I suppose, in some way involved in the parts about the breaks. The removal of an irregular piece of bone which projected under the skin in the first case was followed by disappearance of the groin pain; in the other instance when the patient realised that the pain was probably associated with the old fracture he did not think it of sufficient importance to submit to any operation for its relief.

The cases of *polypus of the rectum* and of *piles* may be taken together. In each case the patient was led to seek advice solely on account of pain in the groin, a fact all the more remarkable because those who were suffering from piles knew of their existence but attached no importance to them, and, indeed, would not have mentioned their existence had they not been questioned on the subject; one patient had, in fact, been referred to me by a practitioner on account of the groin pain, no mention having been made of the existence of piles to him. The groin pain in all these cases was localised at a spot above the saphenous opening; it became worse as the day advanced and was increased by acute flexion of the thigh upon the abdomen. In the hæmorrhoidal cases the cause of the pain seemed obvious; in the others the polypi were discovered only upon examining the rectum on the remote chance of finding a reason for the trouble. In both of these cases, however, rectal discomfort had been felt and in one bleeding had occurred, but the symptoms were not thought of sufficient importance to merit notice. One case of each kind was operated upon with entire success; in the other cases the patients did not think the matter of sufficient importance to submit to the inconvenience of operation.

In the cases of *varicocele*, of which there were five, it was curious that in three the pain seemed to the patient to come from above, whilst in the remaining two it seemed to originate below the level of the pain area. Those in which the pain seemed to originate above were comparatively unnoticeable and were probably of the kind I have described elsewhere in which the most marked dilatation was high up in the inguinal canal.

The two cases of *testicular cysts* (encysted hydrocele of the testicle) are useful in showing how an entirely unsuspected congenital condition may cause trouble without attracting attention to the part at fault. These cysts situated close to the top of the testicle are very common, generally bilateral and quite painless unless by chance they receive some slight injury when they invariably cause discomfort, usually in the groin, which is often very persistent. In each of the two cases included in the table a slight injury to the scrotum had happened years before and had been forgotten; the cysts were of the size of a small cherry, tender on manipulation, after which the pain in the groin was much increased temporarily; both patients were unconscious of the existence of the cysts. In passing it is worth noting that the pain complained of in varicocele is not infrequently due to one of these cysts. I saw within the past 24 hours a case of apparently painful varicocele in which the discomfort was

clearly due to a cyst of this kind on the opposite side; the importance of such a condition in relation to operations for varicocele is obvious.

Although the remaining cases for the most part speak for themselves, some interesting point was associated with each, but your patience and the time at my disposal are alike exhausted.

Collectively this series is, I hope, instructive enough to warrant my having called your attention to it; at all events, it seems to me to justify the following deductions: 1. That pain in the groin as an isolated symptom may arise from causes either so remote or unlikely that their existence would at first sight seem hardly worth consideration. 2. That no examination in a case of pain in the groin can be effective unless it is made in the erect as well as in the horizontal position of the patient. 3. That distinctly localised pain in the presence of obvious organic disease of which the patient is aware may so assert itself as to lead to the gross condition being considered of little or no importance. 4. That the belief in a "functional" or "psychic" pain would be greatly diminished if in all cases of apparently unexplainable pain a more comprehensive search in a detective spirit were made for a cause than is sometimes done.

IDIOPATHIC CYANOSIS DUE TO SULPH-HÆMOGLOBINÆMIA:

(ENTEROGENOUS CYANOSIS).¹

BY SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,

PHYSICIAN TO, AND LECTURER ON MEDICINE AT, ST. BARTHOLOMEW'S HOSPITAL,

AND

THOMAS WOOD OLARKE, M.D.

FOR our knowledge of the peculiar forms of cyanosis with which this paper deals we are indebted almost entirely to the work of a few observers in Holland. The first case was recorded by Stokvis of Rotterdam in 1902, under the title of "Antotoxic Enterogenous Cyanosis (Methæmoglobinæmia?)." He showed the presence of the methæmoglobin spectrum-band in the blood. He also found that the urine contained a substance which gave a red colour with hydrochloric and other acids and transformed oxyhæmoglobin into methæmoglobin. He referred the condition to absorption of a toxic substance, produced by putrefactive changes in the intestines. Talma of Utrecht in the same year reported three cases and showed that the methæmoglobin was intracorpuscular and not, as in cases of drug-poisoning, in the blood plasma. Van der Bergh of Rotterdam, in 1905, showed that Stokvis's substance in the urine was nitrites and a decomposition product of normal urine. He showed also that the band in his own patient's blood was not that of methæmoglobin, but corresponded with that of sulph-hæmoglobin. He referred to a simple means of distinguishing readily between the two by the addition to the blood of sulphide of ammonium.² This caused the immediate disappearance of the methæmoglobin band but not that of sulph-hæmoglobin. He concluded that the condition was due to H₂S absorbed from the intestines, but he was unable to show the presence of H₂S in the blood. He also isolated H₂S-forming organisms from the stools, but attached no value to it, as this could be easily done with normal stools. In the same paper he also recorded a case of methæmoglobinæmia and noted that this condition cleared up in from 24 to 48 hours upon a milk diet but returned in four hours after an ordinary meal. In his next paper he reported that after an operation for stricture of the rectum the patient who was the subject of the first case recovered completely. He also briefly described three other cases of sulph-hæmoglobinæmia, all associated with obstinate constipation and recovering completely when the constipation was cured. In two cases of methæmoglobinæmia also mentioned in the same paper he proved the presence of nitrites in the patient's blood. Douglas and Gibson in July, 1906, recorded a case of methæmoglobinæmia from whose blood they stated that they isolated the bacillus coli communis, and they entitled their paper "Microbic Cyanosis."

The following is the account of the present case. A female, aged 37 years, unmarried, was admitted into St. Bartholomew's Hospital for debility and cyanosis. Although extremely feeble she was able to walk into the ward. The most striking feature in the case was the colour of the skin, which was of a leaden hue, resembling in tint that of silver staining, which made her look when asleep as if she was moribund. The cyanosis was universal, well marked in the face, cheeks, lips, ears, and nose, and under the finger- and toe-nails. The tongue, too, showed the purple colour well. In all parts it was easy to demonstrate that the colour was due to the blood and not to the pigmentation, as pressure with the finger or by bending the nails showed the skin when emptied of blood to be of the normal yellow hue. The fingers were not clubbed. The pulse was regular, feeble, not rapid, and of low tension. The respirations were 20, regular, and quiet. Physical examination revealed nothing. The cardiac dulness was normal. There were no cardiac murmurs. The lungs expanded well, were of normal size, and neither they nor the mediastinum presented any abnormal physical signs. The abdomen was normal and the spleen was not enlarged. The urine had a specific gravity of 1015, contained neither albumin nor sugar, and was of the ordinary colour. The appetite was fair and digestion good; the bowels were habitually constipated, but were kept open daily with medicine. The patient slept well. The only objective sign about the patient, except her feebleness, was the cyanosis, and nothing had been discovered so far which would explain it. There was no sign of congenital morbus cordis or of emphysema. The absence of dyspnoea put out of court any pulmonary disease or mediastinal pressure.

A preliminary examination of the blood in the wards showed the number of red cells to be 4,800,000 per cubic millimetre, of the white 3800, while the hæmoglobin was 90 per cent. The case was therefore not one of polycythæmia, which was on general grounds unlikely because of the patient's pallor. To confirm the results another examination was made a few days later in the pathological laboratory by Dr. F. W. Andrewes, who reported the red blood cells to number 5,050,000 per cubic millimetre, the white cells 3400, and the hæmoglobin percentage to be 115. The differential count was normal—viz., polymorphonuclears 72 per cent., lymphocytes 24 per cent., large mononuclears 4 per cent., and eosinophiles none. The red cells were normal in size and shape and there were no nucleated red cells to be seen.

For a spectroscopic examination the patient was taken into the physiological laboratory and there, with the help of a strong arc light, a spectrum was obtained by Dr. J. S. Edkins through the web of the thumb. This showed what appeared to be the spectrum of methæmoglobin. Subsequent examination by Dr. W. Langdon Brown confirmed this, and the spectrum was easily demonstrated in the blood placed in a microscope cell, so as to obtain films of varying thickness, the two oxyhæmoglobin bands in the green being easily seen in thin films and the band in the red being best seen in a thicker one. By regulating the thickness of the film the three bands could be easily demonstrated in the same specimen.

The presence of methæmoglobin in the blood led to a more careful examination of the urine. Its colour, as stated, was not abnormal, and Dr. Hurtle and Dr. Garrod pronounced the methæmoglobin spectrum completely absent from it. Some blood was now drawn from the patient and centrifuged, so as to separate the serum and cells. Spectroscopically the serum showed no trace of methæmoglobin bands, but they were distinct in the portion containing the red cells. So far, then, the case appeared to be one of intracorpuscular methæmoglobinæmia. Most of the cases of methæmoglobinæmia recorded have occurred as the result of the action of certain drugs—chlorate of potassium, nitrite of amyl, permanganate of potassium, phenacetin, antipyrin, sulphonal, veronal, trional, and others. Consequently the sisters and nurses were ordered to watch the patient and her friends closely, but nothing was discovered. The patient herself denied absolutely that she had ever taken any medicines except what the medical man had prescribed, and the medical attendant stated that except for occasional doses of bromide and iodide he had given nothing for a long time more than a tonic of iron with arsenic. As the patient lived in an isolated part of the country, from which the nearest druggist's shop was some miles away, drugs must have been sent by post if they were to reach her privately. No evidence, however, of the

¹ A paper read at a meeting of the Royal Medical and Chirurgical Society on Jan. 22nd, 1907.

² This is an old test and is mentioned by MacMunn.

frequent receipt of letters or packets by the patient could be obtained either from the family or from the postman. So that all evidence of the obtaining and taking of drugs was lacking. During her stay in the hospital she certainly had no such drugs and her condition after some weeks was not materially changed. Drugs were therefore dismissed as the cause of the condition.

The following history of the case was furnished by Mr. H. F. Steele of Stoke-Ferry:—"The patient has been an invalid for ten years or more. She was very neurotic and suffered chiefly from neuralgia and sleeplessness, with dyspepsia and constipation, and, as a consequence, she became anemic. Her first illness began in July, 1904, when she had a curious nervous attack with delirium and severe pain in the left side of the chest. Previously to this attack she had had bromide of potassium and chloral (20 grains of each) occasionally at night to relieve the pain in the chest and secure sleep. The attack came on suddenly without any apparent cause. There were no rise of temperature and no paralysis. She used to see objects (animals, &c.) in the room, and was at times semi-comatose, though she could always be roused. The attack was not alcoholic. She had for a time hypodermic injections of morphine frequently to give sleep, but after a time the morphine lost effect and was given up. She was ill for about two months and then gradually improved. When convalescent from this attack she was in much the same condition of health as before it. The present illness was of a different character altogether, and commenced in August, 1905, when she became cyanosed gradually and lost strength; the cyanosis at first was observed only during exertion, but gradually became persistent. The weakness slowly increased until she was quite unable to exert herself at all. She became an in-patient for a time in the Lynn Hospital, where the diagnosis, she says, was made of thoracic aneurysm. No drugs appeared to do any permanent good. Iron in various forms, as well as iodides, bromides, and arsenic, were all tried at different times. The only combination that seemed to benefit her at all was iron, digitalis, and strychnine."

In October, 1905, Dr. West saw her when happening to be making a visit in Norfolk. The cyanosis was considerable. She was so feeble and ill that it seemed unwise to disturb her by much examination, for she looked almost as if moribund. The visit was a casual and hurried one and no diagnosis could be made. She looked as if she would die shortly, and when Mr. Steele wrote a year later saying that she was still in exactly the same condition the case was evidently one of great interest and she was readily admitted into the hospital.

Dr. Wood Clarke now undertook to make some further examination of the urine and blood and succeeded in showing that what appeared to be the spectrum of methæmoglobin was not that of met- but of sulph-hæmoglobin, and that the case, therefore, was one of intracorpuscular sulph-hæmoglobinæmia. The following is Dr. Wood Clarke's account of his investigations. The laboratory investigations were directed to the blood, the urine, and the faeces. As cyanosis had been described in connexion with two different forms of hæmoglobin—viz., met- and sulph-hæmoglobin—a preliminary study of them seemed desirable before starting upon investigations into the present case. Accordingly a preparation of methæmoglobin was made by treating a few cubic centimetres of defibrinated ox-blood with potassium ferricyanide, and others of sulph-hæmoglobin by bubbling H_2S through portions of blood for a time or by adding a weak, watery solution of H_2S directly to them. Accurate spectroscopic examination of each was now made. Each showed a dark band in the red, but their positions were different. The methæmoglobin band extended from $\lambda 620$ to $\lambda 645$ on the scale, shading off to $\lambda 615$ on the one side to $\lambda 650$ on the other. The sulph-hæmoglobin band extended from $\lambda 610$ to $\lambda 625$ and in concentrated solution to $\lambda 630$. On Dec. 22nd, and again on the 29th, specimens of the patient's blood were obtained—on the first day from the finger-tip and on the second from a vein in the arm. A few drops were diluted with water and filtered. Each gave a definite band in the red, ranging in the one case from $\lambda 613$ to $\lambda 629$, in the other from $\lambda 612$ to $\lambda 628$. In both cases the band was faint, so that it was necessary to use a solution of such strength that the oxyhæmoglobin bands were blotted out. This made it clear that

the patient's blood contained not met- but sulph-hæmoglobin. This was confirmed by the test referred to by van der Bergh, which consists in the addition to the blood of a little ammonium sulphide; in the case of methæmoglobin the band in the red disappeared immediately, while with sulph-hæmoglobin it persisted, and was indeed somewhat intensified; in both cases the oxyhæmoglobin bands slowly merged to form the band of reduced hæmoglobin.

During the course of the investigation it was noticed that the passage of CO through sulph-hæmoglobin solutions, provided the gas was free from acids, caused a definite change in the spectrum, all the bands being shifted slightly towards the violet end of the spectrum. The two oxyhæmoglobin bands are replaced by those of carbon-monoxide

MHb, Methæmoglobin. SHb, Sulph-hæmoglobin. P.B., Patient's blood. P.D.B., Patient's dilute blood.

hæmoglobin, while the band in the red changed from $\lambda 610$ — $\lambda 625$ to $\lambda 605$ — $\lambda 620$. This test was applied to the patient's blood and the typical change in the bands was noted. The passage of CO through methæmoglobin causes no change in the spectrum. Further investigations upon this property of sulph hæmoglobin are at present being carried on in this laboratory.

An attempt was now made to ascertain if there were any free H_2S in the patient's blood. For this purpose a modification of the method used by van der Bergh was employed. Two wash-bottles were so connected with a suction pump that air could be passed through the solution they contained in series. In the first bottle was placed the solution to be tested for H_2S , and in the second some distilled water containing ammonia. After air had been drawn through the solution for ten minutes the ammonia solution was tested with sodium nitro-prusside. By this means as little as 0.0002 gramme of H_2S could be detected with ease from a watery solution, and it was found that in the ten minutes all the H_2S in the water in the first bottle had been carried over into the second. Five cubic centimetres of ox-blood were now taken; to it was added 0.0002 gramme of H_2S and the test repeated. The presence of free H_2S was easily proved, but the spectroscope showed no sulph hæmoglobin band. To another five cubic centimetres of blood a much stronger solution of H_2S was added; the blood then showed the typical band and continued to do so after all free H_2S had been drawn off. This band was still distinct after the blood had been exposed (a) for 18 hours to the air and (b) for half an hour to CO. Some blood was now treated with H_2S and kept for some hours in a stoppered bottle. From this no H_2S could be obtained. Lastly, it was found that on the addition of a strong solution of H_2S to the blood the

sulph-hæmoglobin band did not appear immediately but only after standing for five minutes. The observations show that the combination of H_2S with hæmoglobin occurs rather slowly, that before the combination has taken place the free H_2S can be removed by a stream of air, but not afterwards. This test tried on the patient's blood gave negative results, from which it may be inferred that if there was any free H_2S at all in the blood, it must have been in extremely minute quantities.

It now seemed desirable to obtain some idea as to the quantity of H_2S required in order to form sulph-hæmoglobin in sufficient quantity to be detected by the spectroscope. A fresh aqueous solution of H_2S was therefore titrated and found to contain 2.856 grammes per litre; 10 cubic centimetres of this solution were repeatedly diluted by halving and replacing with water until a series of solutions was obtained, which represented from 0.01428 to 0.0003 gramme per five cubic centimetres. Ten cubic centimetres of blood were added to each tube, the mixture shaken and divided into two equal portions; one set of tubes was placed in the incubator at $37^\circ C.$ and the other left in the cold room. After 24 hours the specimens of blood were examined with the spectroscope. It was then found that in the blood left in the cold room the band was not visible in the tubes of the fifth dilution, which represented 0.0009 H_2S , while it was clear, though faint, up to the last dilution in the tubes which had been placed in the incubator, representing a dilution of $\frac{1}{10}$ or less than 0.00003 H_2S in the 10 cubic centimetres of mixed blood and water. From these experiments it will be seen that the amount of H_2S required to cause an appreciable change in the blood pigment at body temperature is far below that which can be detected by any chemical means, and consequently that it is no wonder it cannot be demonstrated in the patient's blood.

Blood culture.—Blood was taken from a vein in the patient's arm by Mr. R. C. Emslie on Dec. 29th; with this various media were inoculated but no organism grew.

The urine.—The urine was carefully examined on several occasions. There was never either albumin or sugar present. Indol, by the colorimetric methods of Jaffe and Bouma, was decreased. Ferric chloride gave no reaction. The urine was acid when passed and gave a negative reaction with HCl . Nitrites were present as an extremely faint trace when the urine was acid and in considerable amounts when alkaline. The ethereal sulphates were greatly reduced below the normal, the ratio between these and the mineral sulphates on three separate days being 1:24, 1:35, and 1:26. The total sulphates were normal in quantity. An amyl alcohol extract after the addition of acetic acid showed that there was no increase of hæmatoporphyrin and only the faintest possible band of urobilin. No blood pigments were present. Benzoylation of a litre of fresh urine gave no precipitate.

The stools.—On Dec. 23rd the patient was placed on the Adolf Schmidt test-diet for examination of the stools. At this time the constipation suddenly ceased, and under the influence of magnesium sulphate the stools became copious and watery. It seemed that during this period the cyanosis became less marked. The stool obtained, which probably also contained urine, was large and fluid, and had a decidedly offensive odour. It was slightly alkaline in reaction. On being rubbed in a mortar and examined on a black plate a few small shreds of connective tissue and mucus were found. Meat digestion was complete. On treating with Lugol's solution no undigested starch granules were to be found. The addition of 30 per cent. acetic acid and heat demonstrated that there was no excess of fat in the stools. No fatty acids were seen. A few grammes of stool placed in a Straßburger fermentation apparatus and left in an incubator at $37^\circ C.$ did not develop an appreciable amount of gas in 48 hours. At the end of this time the reaction was about as strongly alkaline as at the beginning. Testing the stool after 48 hours with ammonia and sodium nitro-prusside only a slight pink colour was obtained, while the water in the collecting tube of the apparatus was quite free from H_2S . A second specimen of stools obtained on Jan. 5th was soft, dark green in colour, and of unpleasant odour. Microscopic examination showed the same findings as before, except for a few undigested starch granules. A faint trace of H_2S was proved after fermentation.

In the attempt to determine whether there were an increase in the sulphuretted-hydrogen-forming organisms in the

patient's intestines the following method was used at the suggestion of Dr. Andrewes and under his direction. One gramme of solid stool was weighed in a sterile watch glass, thoroughly ground up in a sterile mortar, and washed into a flask containing 99 cubic centimetres of sterile water. This was then diluted decimally through ten flasks and one cubic centimetre of the fluid in each was added to a bouillon tube containing 0.5 per cent. lead acetate. The cultures were grown at $37^\circ C.$ for 48 hours anaerobically and 48 hours aerobically. With one patient's stool blackening from lead sulphur appeared up to a dilution of 1:10,000,000—i.e., one cubic centimetre of the fluid contained 0.000001 gramme of stool—while with four controls taken from other patients on the same diet and drugs it varied from 1:10,000 to 1:1,000,000,000. The experiments were too few to be conclusive, but they suggest that in this patient there was no increase of H_2S -forming organisms in the intestines at the time of the examination.

The accompanying table gives an analysis of 13 cases, eight of methæmoglobinæmia and five of sulph-hæmoglobinæmia. In the first four cases recorded of methæmoglobinæmia the exact nature of the condition is a little uncertain, as at that time the distinction between met- and sulph-hæmoglobinæmia was not recognised. Taking the two groups together, we find that eight of the patients were men and five were women, but of the five sulph-hæmoglobinæmic cases four were women and only one was a man. All the cases were adults except two, a boy, aged nine years, and a girl, aged 17 years. With these exceptions the ages ranged from 29 to 67.

The chief symptoms beside the cyanosis were headache and general weakness. The weakness was often extreme and in two cases was described as a "feeling of paralysis of the arms and legs." The cyanosis was general but especially conspicuous in the mucous membranes. There were no respiratory or cardiac symptoms other than the weakness would account for. Clubbing of the fingers was observed in two cases. The symptoms were usually of gradual onset, but occasionally developed very suddenly.

The duration of the cases varied from six months to eight years. Of six cases in which the result is recorded five got well and one died. In the fatal case the only lesions discovered at the necropsy were ulcerative enteritis and chronic parenchymatous nephritis.

The blood count is given in five cases. In four the red cells were 5,000,000 per cubic millimetre or slightly more, in one 3,360,000, so that in spite of the pallor there was no real anæmia; the white cells were 7900 per cubic millimetre in two cases, 10,000 in one, 20,000 in one, and 3400 in another. The hæmoglobin percentage was given in four cases as 90, 96, 70, and 115. The differential blood-count in one case was normal.

The urine showed the presence of albumin in three cases as a trace only except in the fatal case, in which chronic parenchymatous nephritis was found post mortem. Indol was in excess in four cases and in defect in two cases. The ethereal sulphates were increased in one case and diminished in one case. The pigments were not abnormal either in amount or nature.

Contrasting the two groups, it would appear that the methæmoglobin cases were associated with diarrhoea and improved greatly on a milk diet, while the sulph-hæmoglobin cases were associated with constipation and did not improve till this was relieved. In van der Bergh's first case of sulph-hæmoglobinæmia, that of a boy, aged nine years, the constipation depended on a rectal stricture which resulted from an operation for imperforate anus. A second operation, which relieved the stricture and constipation, was followed by recovery.

A SUMMARY OF PREVIOUS INVESTIGATIONS.

The first case recorded by Stokvis was that of a soldier who had been cyanotic for five years, the condition being associated with chronic diarrhoea. The patient died, but the necropsy showed only ulcerative enteritis and chronic parenchymatous nephritis. Spectroscopic examination of the patient's hand and tongue showed distinctly the band of methæmoglobin. As the action of drugs could be excluded, Stokvis concluded that the condition was due to intestinal absorption, and he turned his attention to the urine as the most likely source of information as to the etiology of the methæmoglobin-forming substance. On adding 1 cubic centimetre of defibrinated ox-blood to 25 cubic centimetres of the patient's urine he was able to obtain methæmoglobin

* Cases 1, 2, 3, and 4 are entered as MHb cases, though the fact that sulph-hæmoglobinæmia had at that time not been described makes it possible that they were the latter condition.

REMARKS.—Case 1: Necropsy.—Ulcerative enteritis; chronic parenchymatous nephritis. Case 5: Operation on rectal stricture. Case 6: Condition cleared up temporarily on milk diet. Cases 7, 8, and 9: Cleared up as soon as the bowels were kept open. Case 10: Condition cleared up temporarily on milk diet. Case 11: Condition cleared up temporarily on milk diet. Case 12: Previous history of the use of aniline drug.

in ten minutes. He further found that the addition of hydrochloric, phosphoric, sulphuric, and nitric acids to the urine produced a deep red colour. These two reactions occurred only when the urine was alkaline. An examination of the ethereal and mineral sulphates showed that the former were greatly increased over the normal, the average ratio being 1:2.79. The amount of indican was in excess. From these findings he concluded that the substance in the urine which gave the red colour with acids was a product of intestinal putrefaction and was the toxic material which caused the change of oxyhæmoglobin to methæmoglobin in the blood. Repeated efforts to isolate this substance failed completely.

Talma's three cases of methæmoglobinæmic cyanosis were associated with long-standing diarrhoea. He added to our knowledge of the condition by proving that the methæmoglobin was in the blood corpuscles and not in the plasma, as is usually the case in drug-poisoning. As in the urine of all

his cases he found an increase of indol and skatol he accepted Stokvis's opinion as to the cause of the disease.

By Hijmans van der Bergh's researches considerable light was thrown on the subject. In his first paper he reports two cases. The first was that of a boy, aged nine years, who suffered from a rectal stricture and urethro-rectal fistula following on early operation for imperforate anus. After proving that the altered blood pigment was intracorporeal he turned his attention to the urine. Referring to recent work of Steensma and older work of Schönbein and Röhmman, he showed that normal urine in the process of putrefaction gives off nitrites—powerful methæmoglobin-forming substances—and is turned red by the addition of strong hydrochloric acid, and that, furthermore, the addition of a small amount of sodium nitrite to a normal acid urine gives it the property of being turned red by acids. He therefore concluded that the substance which Stokvis put forward as the cause of the

are often preceded for 10 or 20 minutes by some interference with vision. This in many cases amounts to no more than a sudden diminution of visual acuity, with a sensation of blackness or dancing specks before the eyes. Others have a more fully developed visual spectrum with partial blindness to one side, with the well-known fortification spectrum in the blind field. In others, again, there may occur a sudden hemianopia, a complete blindness to one side, so that the patient sees only half of the object directly looked at, so that if he looks into a mirror he can see only one half of his face. In a few patients there may be noticed also tingling of the fingers and of one side of the face, with perhaps aphasia, lasting for a few minutes. The usual course of these headaches is well known, lasting usually during the whole of the day, prostrating the patient completely, until vomiting brings relief. The cessation of the headache is probably not dependent directly upon the vomiting, for in a certain number of cases vomiting occurs quite early after the commencement of the headache and may be repeated several times, with no amelioration of the headache until many hours after. On the other hand, the vomiting in migraine is more probably the result of the headache, inasmuch as both are the result of increased intracranial pressure due to the vascular engorgement. When the headache has already lasted several hours and the vaso-motor derangement is beginning to subside, then the act of vomiting does no doubt contribute towards the cessation of the headache, on account of the powerful effect that vomiting produces of general vaso-dilatation, thus relieving the cerebral arterial pressure.

True migrainous headaches very commonly commence in early childhood and last until well past middle life, recurring at varying intervals, but usually diminishing in severity as the years pass. If gout, tuberculosis, or other cause of frequent pyrexia supervene, the headaches as a rule disappear. Probably the beneficial action of a seton in the back of the neck, an old remedy which often gave very good results, is due to the slight amount of chronic suppuration and consequent pyrexia that it produces. If the sick headaches increase in severity and frequency in middle age probably there is present some additional factor, as chronic Bright's disease or arterio-sclerosis, which is very prone to develop insidiously and aggravate a symptom, such as periodic headache, that is already present.

Migrainous attacks often come on without any previous warning, just as epileptic attacks so often do, the patient being apparently in his usual health or even conscious of an excessive sense of well-being. The attacks are, moreover, frequently precipitated by the same causes that are liable to bring on a fit in an epileptic subject—viz., great excitement, late hours, a crowded room, a bout of drinking, or, in women, the menstrual period. Constipation is by no means always present, and the tongue is often clean at the commencement of the attack, and there is no reason to ascribe this class of case to a toxæmia of intestinal origin. Very occasionally there may be loss of consciousness, or, more commonly, the sufferer from migraine has a typical epileptic fit. More rarely cases are met with in which epileptic fits are regularly preceded by a hemianopic scotoma or visual spectrum indistinguishable from that met with in migraine. Rarely of all are epileptic attacks which are followed by hemianopia, which is transitory and clears up entirely in 24 hours. Such varied forms of transitory cerebral disorder show clearly that migraine and epilepsy are closely allied, and that the same pathological process is probably concerned in the production of both. If the periodic headaches are of frequent recurrence, they are treated best between the attacks with bromides on the same lines as a case of epilepsy would be treated. Perhaps the three bromides of ammonium, sodium, and potassium answer somewhat better than potassium or sodium bromide alone. The actual headache is often relieved best, if taken sufficiently early, by a stiff dose of butyl chloral hydrate and phenazone, but if it is not given quite early in the headache, or preferably during the preliminary stage of scintillating scotoma, the dose is likely to lie in the stomach unabsorbed, perhaps for hours, and finally to be vomited unchanged. Another drug that may often bring almost immediate relief is nitro-glycerine, which by its vaso-dilator effect lowers the blood pressure in the peripheral vessels and so reduces the cerebral arterial pressure. This effect of vaso-dilatation in true migraine is of some help in understanding the pathology of the condition. Probably what takes place is an initial vaso-motor spasm affecting

more particularly the territory of one posterior cerebral artery. During this stage the visual phenomena are produced by anæmia of the half-vision centre in the occipital lobe. The primary stage of arterial spasm is succeeded by vascular engorgement, thus directly producing the headache which, like the vaso-motor disorder, is often unilateral. In a few cases the primary spasm is very slowly relaxed, with no succeeding state of engorgement, as in a case I have now under observation of a woman, aged 35 years, who has for many years been subject to attacks of temporary blindness lasting one or more hours, the sight gradually returning, and as a rule little or no headache following. This theory of a primary spasm of the arterial supply in the region of the half-vision centre in the occipital lobe is strongly supported by the following case. A young woman who for many years had been subject to infrequent attacks of migraine, after one attack developed hemianopia. In this case no doubt, the primary spasm precipitated a thrombosis in the branch of the posterior cerebral artery supplying the half-vision centre in the calcarine cortex of one side. Hers was a family type of migraine, her brother occasionally suffering with very severe attacks. Another woman, a hospital out-patient, aged 48 years had been subject to severe periodic headaches from early childhood recurring about once a fortnight, and followed by sickness and disorder of vision. These recurrent attacks became less frequent after she reached the age of 30 years, occurring after that only once in six months until five years ago when she was operated on for enlarged glands of the neck. Since that time the attacks completely ceased, but three years ago she had a stroke followed by slight left hemiplegia. Six months later she had a slight fit with twitching of the right side of the face without loss of consciousness, but right hemianopia developed, which has remained permanent. These two strokes were undoubtedly thrombotic and are additional evidence of the liability to vascular derangements in the region of the calcarine cortex in these cases. Her visual symptoms in the migrainous attacks were not, however, hemianopic, but merely progressive disturbance of vision to the point of complete inability to distinguish objects, increasing with the continuance of the headache up to the period of vomiting. This is a not uncommon form of visual disturbance to meet with in that form of migraine which does not begin with the characteristic hemianopia or scintillating scotoma.

Next I wish to refer to periodic headaches which may resemble true migraine somewhat closely and yet are less dependent upon an hereditary neurosis and paroxysmal vaso-motor spasm than upon some peripheral cause which by its local irritant effects may set up reflexly a migrainous attack. These cases, pathologically speaking, would be strictly analogous to reflex epilepsy, such as convulsions dependent upon the peripheral irritation of worms, the irritation of a scar, &c. They are, of course, more likely to occur in patients with a neurotic family history, but the point I wish to make is that although the attack of migraine resembles true migraine, yet the peripheral cause in these cases is the most important element in their causation, and the removal of this may be followed by complete cure of the periodic headaches. A typical example of this form is ophthalmoplegic migraine, sometimes known as recurrent third-nerve paralysis. In this disease the third cranial nerve on one side has been damaged in some way, as by a small hemorrhage from a severe blow on the head or fall in infancy, leaving behind a patch of meningeal thickening. At intervals the patient is attacked by severe headache which lasts for a day or two, and at the same time the third nerve becomes completely paralysed, though it recovers slowly during the succeeding weeks. This type rarely, if ever, develops a visual spectrum, which is a much rarer symptom in reflex than in hereditary migraine. Typical periodic headache resembling migraine I have known to follow an injury to the skull, causing a fracture of the base. The man recovered apparently from his injury but became subject to fortnightly headaches which prostrated him for the whole day. A year later he died from cerebral abscess. Other peripheral causes that not uncommonly give rise to this type of periodic headache are visceral lesions, such as chronic appendicitis, gall-stones, chronic gastric and other intestinal derangements. The onset of the menstrual period, too, in women is a frequent determining cause of reflex headache, especially if there be any chronic uterine disorder. The following case is interesting

on account of its suggestive analogy between reflex epilepsy and a reflex migraine. A boy, aged 14 years, had numerous convulsions in infancy; at the age of two years he was deeply jaundiced and ever since that time has been subject to recurring "bilious attacks." These occur every two or three weeks and commence with pain round the right side, being followed by severe headache which completely prostrates him for several hours, the attacks ending with vomiting. Occasionally in the course of an attack he becomes convulsed, with complete loss of consciousness—that is to say, an epileptic fit sometimes alternates with a migrainous headache, whereas the preliminary aura of pain round the right side and the history of the case dating from jaundice at the age of two years suggest that the attacks are of the reflex type and are perhaps dependent in part upon some lesion in the neighbourhood of the liver acquired at that early age, such as adhesions around the gall-bladder. The case is now under observation and the question as to the possible relief of the symptoms by an exploratory laparotomy in the region of the right hypochondrium is being considered.

The assertion has been made by some ophthalmic surgeons and others that the large majority of, if not all, migraines are due to errors of refraction, and that the sole remedy necessary which will provide an infallible cure is a pair of proper spectacles. This is a most pernicious way of explaining the condition because of its apparent simplicity and because of its striking success in a certain proportion of cases. Ocular headache, in which the pain is usually situated over one or both eyebrows and is due to errors of refraction, especially astigmatism, is not uncommon. Every now and then the pain may be more periodic in some patients and may exhibit the course of symptoms familiar to us as migraine. In these cases we have to do with a reflex migraine the peripheral exciting cause of which is the visual defect and constant unequal strain upon the ciliary muscle, and these patients will probably get much relief from proper correcting glasses. I have recently had under treatment a medical student for severe migraine, preceded by scintillating scotoma, whose first attack occurred two years ago while recovering from ulceration of both cornea. In this case undoubtedly the peripheral exciting cause was the astigmatism produced by the scarring of the ulcers on the cornea. For several weeks the attacks were frequent and severe, but they have now practically disappeared with the improvement in his vision.

After what I have previously said on the subject of hereditary and reflex migraine it would be manifestly absurd to ascribe all migrainous headaches to errors of refraction and the lack of proper correcting glasses. This is only one of the many peripheral organic defects which may reflexly induce the attacks. The reflex migraines differ from the true hereditary migraine in that they may start later in life, being dependent upon a peripheral cause in large part which is not hereditary. I have, however, known this form which had been present from early childhood disappear after a diseased appendix had been removed. The treatment of these reflex headaches is, therefore, obviously to remove if possible the peripheral irritant cause, whereas phenacetin and other analgesic powders are mere attempts at palliation of the periodic symptoms.

Constipation is an extremely common cause of headache and though it may accompany migraine and may even determine its onset it is one of the less frequent causes of periodic headache resembling migraine, but rather of toxæmic headache, which is more constant, often daily in its occurrence. A very definite type of recurrent toxæmic headache, which may easily be mistaken for migraine, is that associated with sluggish liver and habitual constipation. The pain in the head, as in migraine, is extremely severe, prostrating the patient completely for about 24 hours, and the tendency to these headaches may run in families, increasing the liability to confusion with migraine; but they differ from this neurosis in the following important particulars. There is no evidence of neuroses in the family; the periodic headaches get worse in middle life instead of better; there is no preliminary visual spectrum, though the patient may complain of a certain amount of dimness of vision; there is the close association of the headaches with constipation, furred tongue, foul breath, sallow skin and conjunctivæ, while the headaches may be warded off by a cholagogue and saline aperients and are not influenced by phenacetone, phenacetin, bromides, or the usual headache powders.

There is no arterio-sclerotic factor in this type of headache, the pulse remaining quite soft, and there is no albuminuria. The sluggish liver action and the constipation are the key to the treatment, yet there is a curious cycle of symptoms. The headache will pass off in about 24 hours or so, even though the bowels be not relieved, and the patient then feels quite bright and clear-headed. After one or two days a slight dull frontal headache returns, especially in the morning, and after an interval varying in different persons, but often fairly constant for the same individual, the severe headache recurs. This recurrent cycle of symptoms ending in the explosion of headache is apparently due in large part to a functional disturbance of the liver, the periodicity of the symptoms suggesting some derangement of its nervous control.

Toxæmic headaches are due to a circulating blood poison which may be introduced into the blood from without, such as alcohol, lead, iron, or ether, or the poison may be manufactured within the body either as the result of some acute microbic infection as pneumonia, typhoid fever, influenza, or small-pox, or as the result of some chronic morbid process as chronic gastritis, chronic Bright's disease, gout, diabetes, or cirrhosis of the liver. Gout and arterio-sclerosis are both very common causes of chronic headache, the high arterial tension in the latter being a most important contributory cause. The headache in arterio-sclerosis may be most persistent and resistant to ordinary treatment, though it may at once yield to nitroglycerine or one of the other nitrites, through the resulting lowering of blood pressure. In chronic Bright's disease, especially the contracted granular variety with hard arteries, the headache is equally severe and persistent, in part due to the high blood pressure and partly due to a toxæmia secondary to the kidney disease. Indeed, there are only two other causes of headache so severe and persistent as that of chronic Bright's disease with arterio-sclerosis—namely, cerebral tumour and cerebral syphilis. The headache associated with gout is not always associated with high arterial tension, but is often due to a toxæmia dependent upon a faulty metabolism and appears to be caused by the circulation in the blood of purins and other uric acid antecedents derived from a diet containing an excess of these bodies. These uric acid antecedents are chiefly derived from an excessive meaty diet, though they are also contained in tea and coffee. For persons, especially those of sedentary habits, with large appetites who are complaining of frequent morning headache it will be well in certain cases to insist on a rigid purin-free diet of milk, eggs, cheese, butter, cream, bread, nuts, macaroni, potatoes, and green vegetables. Such patients should drink a small tumblerful of some good laxative saline, taken hot the last thing before going to bed. With a weekly dose of calomel or blue pill and a short walk before breakfast every morning relief may often thus be obtained from the persistent distracting pain at the top and back of the head which, in men over 40 years of age, is frequently the result of long-continued excess of proteid constituents in the diet. It is possible that excess of the other constituents of food besides proteid—namely, the fats and carbohydrates—may, as Hare has suggested, be responsible for a similar process of toxæmia, which he has named "hyperpyræmia." Thus excess of all forms of food, not only proteid but fats and carbohydrates also, is likely to lead to overloading of the liver, and finally of the excretory organs, the kidneys. The postulate that the large majority of people habitually eat too much may be taken as in a fair way of being proved, since the researches of Chittenden on metabolism and the calorific values of diet, on the lines preached by Fletcher, have shown that the average individual can maintain perfect health and strength, while doing fair muscular work, on a diet the calorific value of which is not more than from one-half to two thirds of that usually accepted as the irreducible minimum. Lastly, the effect of an open-air life has scarcely received sufficient prominence in the treatment of many forms of toxæmic headache. Persons who are subject to chronic headaches should cultivate the habit of keeping their windows widely open, and the hardening process thus slowly applied will not only render the individual far less susceptible to catching ordinary colds but his tendency to frequent headaches will often completely disappear, and from a listless valetudinarian with always something wrong with him he will become brisk and healthy in mind and body.

Wimpole-street, W.

ON OPSONINS AND THE OPSONIC INDEX
AND THEIR PRACTICAL VALUE IN
THE TREATMENT OF DISEASE,ESPECIALLY WITH REGARD TO PULMONARY TUBERCULOSIS
IN SANATORIUM PATIENTS.¹

By GEORGE A. CRACE-CALVERT, M.B. LOND.,

PHYSICIAN TO THE VALE OF CLWYD SANATORIUM, RUTHIN,
NORTH WALES.

THE human body is subject to infection by the micro-organisms of many diseases, but of the multitude of organisms which affect man there is scarcely one which is more common than the tubercle bacillus, and because my work brings me almost solely into contact with patients suffering from pulmonary tuberculosis I propose to base my remarks chiefly on work that has been done in connexion with the tubercle bacillus and on the efforts that have been, and are being, made to combat its ravages.

As is well known, tuberculosis may be acute or chronic, and I use these terms rather than "general" or "local," because though general tuberculosis is practically always acute, yet local tuberculosis may be acute (as tuberculous meningitis, &c.), or it may be chronic (as in ordinary pulmonary tuberculosis, tuberculous glands, &c.). Now, in all the common general infections the disease, as a rule, only lasts a short time and if the patient's strength can be maintained for this short time recovery takes place, because the presence of the toxins in the blood leads to the corresponding formation of antitoxins which are incompatible with the life of the infecting microbe. If, however, the patient's strength cannot be maintained we believe that there is not time for a sufficient production of antitoxins to neutralise the toxins and so death ensues. In the local infections, however, the disease as a rule lasts a long time for, owing to the circumstances of the case, there is only a small production of toxins with a corresponding small absorption into the blood and hence there is only a limited production of antitoxins because the blood and tissues are not stimulated to produce them. It follows then that in the treatment of acute or general infections we must adopt chiefly the expectant attitude and maintain the patient's strength and trust that the infected organism may be able to produce sufficient antitoxins to neutralise the toxins, though in a few cases—e.g., diphtheria and septicæmia—we can produce the antitoxins externally to the organism and by inoculating them into the patient increase his available resources for fighting the disease. In the treatment of the chronic or local infections, however, we must stimulate the organism to produce its own antitoxins, and one of the readiest methods of doing this is by the introduction into the tissues of the toxins of the disease in question. Now at present it is difficult to separate the toxins from the micro-organism producing them and we accordingly must make use of a sterilised suspension of the micro-organisms themselves which contain the toxins. If we can safely do this we give the patient a better chance of recovery, because we can regulate the dose of toxin employed without running the risk of overwhelming his powers of resistance as so often happens in the case of an acute general infection. But to do this we must be able to estimate the power of resistance of a particular patient to a particular disease, and this is what Sir A. E. Wright has enabled us to do by his process of estimating the opsonic index. Metchnikoff believed that the phagocyte was the all-important factor in enabling an infected organism to combat any disease, but Wright has shown that the phagocyte is practically useless without the presence of a certain substance in the serum to alter in some way the pathogenic microbe. He calls this substance "opsonin" and terms the amount present in any blood the "opsonic index" of the blood.

Apparently there are opsonins for every microbic disease present in the blood and only the opsonin for the particular disease is affected by the presence of the toxins of the infecting microbe, the others remaining about normal. This statement requires a little qualification, as Dr. T. R. Bradshaw of Liverpool found that inoculations of anti-diphtheritic and antitetanic sera caused a depression of the tuberculo-opsonic index which lasted for some months. He was inclined to assume that it was "due to some property

inherent in the blood of the horse and has nothing to do with the specific antitoxins."²

At present we cannot measure the amount of opsonin quantitatively but only qualitatively as follows, and I shall describe the process very briefly. We must prepare (1) a solution of white blood corpuscles by centrifuging a mixture of a few drops of any human blood in a small quantity of normal saline solution to which has been added 1 per cent. sodium citrate. The supernatant fluid is syphoned off and the corpuscles are then washed in normal saline solution alone and centrifuged and the supernatant fluid is syphoned off, leaving only blood corpuscles, chiefly red with leucocytes in the upper layers. 2. An emulsion of the microbe towards which the opsonic index is to be estimated. This is made by rubbing up a culture (or in the case of tubercle bacilli the dried bacilli) in saline solution of 1.5 per cent., to form an emulsion, which is then diluted to the proper strength, which can only be learnt by practice. 3. Some of the patient's serum is obtained by allowing a few drops of his blood to clot in one of Wright's capsules. Equal volumes of these three are fixed in a capillary pipette and incubated at blood heat for from 10 to 15 minutes, then mixed on a slide, and an ordinary blood film is made on a glass slide which has been rubbed over with finest emery paper. The film is fixed in saturated mercuric perchloride solution, washed, stained in carbol-fuchsin, decolourised in 2 per cent. sulphuric acid, washed in water and then in 0.1 per cent. sodium carbonate, and counterstained in methylene blue. The leucocytes are found at the edge of the film and the number of micro-organisms in 50 of the polynuclear cells is counted under the microscope. An exactly similar proceeding is adopted, only using the serum of a normal man in the place of that of the patient. The opsonic index is obtained by dividing the number of engulfed organisms in the patient's slide by the number in the normal slide.

It has been found that the opsonic index in normal healthy people (who are apparently free from tuberculous infection) varies between definite limits, and Bulloch,³ who examined many cases, put these limits as from 0.8 to 1.2. Urwick confirmed this in about 20 cases and I have found practically the same figures correct in seven persons and all except one are well within these limits. In one case where at two days' interval it was 1.3 I cannot find any satisfactory explanation as the man is apparently quite healthy without any predisposition to tuberculosis. Urwick⁴ in 33 cases of all stages of pulmonary tuberculosis found that the opsonic index was usually higher than normal, and this is probably owing to auto-inoculation from injudicious exercise and work, and with auto-inoculation we probably get a high index when the immunising machinery is strong and a low one when it is weak.

I do not know of any estimations of the opsonic index in persons predisposed to tuberculosis because I suppose that such cases are not easy to obtain with a subsequent confirmation of the diagnosis by actual development of the disease, but we may almost certainly presume that the opsonic index in such persons is low—i.e., that their resistance to the disease is feeble, and hence they sooner or later fall victims to it.

With regard to our sanatorium cases I have divided them into several classes and I shall deal with each in turn.

1. In ten early cases with a small amount of mischief only, whose indices I have estimated as soon as they came. I have found that six of them have an index which is normal or above and four have an index below normal. In all except one case the index is within the normal limits (0.8-1.2) and I do not see that the estimations would have been of much service in diagnosis. Of course, if the index is above or below these limits or varies from day to day I think that the diagnosis of tuberculosis is practically certain, though in the series of normal persons mentioned I had one with an index of 1.3. So far as I have yet observed this difference in the opsonic index does not seem to make any difference in prognosis, as all these cases have done, or are doing, well with ordinary sanatorium treatment. After treatment by sanatorium methods for varying periods (without any inoculations of tuberculin) the index has risen in three cases and fallen in three, though in three of them the disease was not arrested when the patients

¹ A paper read before the Manchester Medical Society.

³ THE LANCET, Dec. 2nd, 1905, p. 1623.

⁴ Brit. Med. Jour., July 22nd, 1905.

left the sanatorium. In the case of the other indices they are about equally divided—above and below normal—but I do not know what they were when the patients came. From these figures it is difficult to say what effect sanatorium treatment has on the opsonic index, for it probably depends on the index on arrival and this, again, depends on the amount of auto inoculation from exercise, work, &c., that the patient has undergone before coming to the sanatorium.

2. In acute pulmonary tuberculosis where there is a high temperature and the patient is apparently going downhill rapidly we get an index which varies from day to day. This variability is due to auto-inoculation which causes not only a fluctuating index but also a high temperature, but because a patient has a high temperature one cannot assume a fluctuating index, as we have a case at present where the temperature is high while the tuberculo-opsonic index is steady, the temperature being possibly due to staphylococcal infection. We have had three of these acute cases where we have been able to estimate the indices. In the first case we were only able to make a few estimations as we sent the patient home because he was rapidly losing ground. In the second there was extensive mischief in both lungs with high temperature and the index fluctuated greatly. He left us after four months to go to a sanatorium in the south of England where it was warmer, but just before he left his temperature showed signs of falling. At the other sanatorium his temperature continued to fall and he was soon on exercise and gradually improved. He returned to us in July with his lungs much quieter, a good temperature, and a lower and steadier index. Two months' later his lungs were quieter still, his temperature was better, and his index was keeping steady. In the third case there was a history of irregular life and much alcohol with extensive acute mischief of short duration with cavitation, high temperature, and an irregular fluctuating index. With two months' rest in bed and three months' further rest on a couch in the garden the lungs quietened considerably, the temperature fell to normal, and the index became steadier. These cases, then, seem to show that a fluctuating index is a sign of acute mischief and that as the case improves and the mischief quietsens the index becomes steadier and tends to approach the normal line. They also show to a certain degree that the ordinary fluctuations of temperature have nothing to do with variations in the opsonic index, as already shown by Urwick, Lawson, and others.

3. In ordinary sanatorium cases where there is a fair amount of disease in a subacute state we get an index which is usually about normal. Lawson and Stewart⁵ found in 24 out of 25 cases that the index was low but we have usually found that it is just above normal—i.e., above in 14 cases and below in seven—and, so far as I can see, this difference in indices does not correspond to a difference in the acuteness of the case. In these cases there may be an absence of stimuli from auto-inoculation or the immunising machinery may be worn out, but I think that the former is the correct cause, because if these cases are inoculated with tuberculin the opsonic index usually rises and by suitably spaced inoculations can be kept raised.

4. In the class of cases called "sanatorium cures," more properly arrested cases, Bulloch⁶ found the index depressed in 13 out of 14, while Lawson and Stewart⁷ found in 30 cases cured in a sanatorium without inoculation that the index varied from 0.5 to 2.1, 17 being 1.0 or above. In four old cases I have found the index above normal in three and below in one, the latter having been well since 1900 and possibly approximating to a normal person. This question of the index in a "cured" patient is important because if it be more usually found low it seems as if the patient's resistance was not permanently affected by treatment, and that he therefore runs a risk of further infection, but before accepting this as a definite statement we want to know if the cases were truly arrested and not simply patched up temporarily, and also what their index was before they started treatment—a point that cannot be settled yet as the method of estimating the opsonic index has not been in existence long enough to secure any results.

5. In cases of tuberculous glands Wright has, so far as I know, invariably found the index to be low, and Bulloch⁸

in two cases found it to be 0.3 and 0.6. In one case of tuberculous cervical glands and in one of tuberculous mesenteric glands we found the index low, though in neither case was it as low as Wright and Bulloch seem to have obtained.

6. In one case of tuberculous enteritis (apparently), where there is a very little subacute lung mischief, we obtained an index below normal at first, but there seems to have been auto-inoculation at short intervals because the index has fluctuated and these fluctuations correspond more or less closely with attacks of acute abdominal pain, slight diarrhoea, and a rise in temperature.

Of course, there are other tuberculous affections, such as lupus, disease of the joints, larynx, genito-urinary system, and also diseases due to infections by other organisms, but as I have had very little practical experience of these cases I do not propose to say more than a few words about them incidentally later, but shall leave them in the hope that others may tell of their experience.

Now having shown what the opsonic index is and how it varies in different cases of tuberculous disease, I must pass to the practical bearing on the treatment of such cases and I must deal with each of these classes in turn and show how estimations of the opsonic index may help us. It must be obvious to everyone that it is desirable to raise the opsonic index to normal or above, especially in those cases where it is low, for as the plasma is the fluid which bathes all the tissues of the body and as the opsonin exists in the plasma and is the means of altering the invading micro-organisms so that they can be taken up by the phagocytes, it follows that a plasma rich in opsonins will be a powerful means of enabling the organism to resist the ravages of the micro-organisms, and therefore we may safely say that a high opsonic index is of undoubted value if it can be maintained for any length of time.

Wright⁹ has shown that the opsonic index can be altered in either direction by an appropriate dose of the appropriate vaccine. He defines a vaccine as "a sterilised and standardised suspension of micro-organisms" and it is made as follows: The micro-organism, be it staphylococcus, tubercle, or any other kind, which is found in the blood or tissues of the patient, is grown until a pure culture is obtained. Then a small quantity of the growth is rubbed up with normal saline solution to which 0.25 per cent. of lysol is added and the whole is heated to 60° C. for an hour to make sure that all the micro-organisms are killed. This is then standardised by counting it against a small quantity of blood where the number of red blood cells is approximately known. In the case of tubercle bacilli Koch's T.R. practically corresponds to this description as it consists of finely ground-up bodies of dead bacilli and hence it is used as the vaccine in tuberculous diseases after appropriate dilution.

When a patient is inoculated with a vaccine there is almost invariably at first a drop in the opsonic index (negative phase) which lasts from a few hours to 14 days, but this is followed by a rise in the index (positive phase), usually to a higher level than it formerly stood at, and this is maintained for a varying time, being succeeded by a gradual fall back to about the original, though often there is a slight permanent increase. Wright found that it was possible to accumulate negative phases and is inclined to attribute the unfortunate results that occurred when Koch's T.R. was first introduced to the large doses frequently employed, causing an accumulation of negative phases. So far it has not been found possible to accumulate positive phases, but by the use of judicious inoculations and frequent estimations of the opsonic index one positive phase can be followed by another with only a short slight negative phase in between. If we wish, therefore, to get the best results from our inoculations we must estimate the index frequently and use appropriate doses of vaccine. For the first condition we must have our patient under constant observation, so that the index may be estimated daily, if necessary, and so that auto-inoculation due to injudicious exercise may be avoided. Exercise undoubtedly affects the opsonic index, for Ellett¹⁰ showed that in men training for a boat race there was a considerable fall of the index when they finished their day's outing as compared with that before they went out. Then, again, Meakin and Wheeler¹¹ showed that in sanatorium patients exercise is followed by auto-inoculation causing

negative and positive phases and I have confirmed this in a few cases.

As regards the appropriate dose of vaccine, this can only be learnt by experiment and repeated estimations of the index, but it has been proved that the large doses (i.e., $\frac{1}{10}$ of a milligramme and upwards) recommended in the directions given with Koch's tuberculin are too big and that very good results can be obtained with a very much smaller dose, and we have had a patient whose index responds readily with a dose of $\frac{1}{100}$ of a milligramme, though the more general dose that we use is $\frac{1}{10}$ of a milligramme. With small doses such as these the negative phase is absent (or more probably very short) and there is, as a general rule, no rise of temperature. In one case after the first inoculation of $\frac{1}{10}$ of a milligramme there was a good rise of temperature which, however, did not occur after the next inoculation of $\frac{1}{10}$ of a milligramme, but then this patient was an extremely nervous individual who had been imagining all sorts of horrors as to the process and results of inoculation. In another case several inoculations were followed by no rise of temperature and I believe that this is the more usual course of events. Auto-inoculation, too, probably occurs without any rise in temperature except when it is due to a fresh infection.

As regards the frequency of inoculation, this depends on the length of time that the positive phase lasts, and we usually find that at first we have to inoculate at about from seven to ten days' interval, while as the number of inoculations increases the frequency is diminished, until we have had a positive phase lasting two months after an inoculation of $\frac{1}{10}$ of a milligramme.

If we now consider the various classes of case in turn we come first to that of persons *predisposed* to tuberculosis. In these cases, after due estimation of the opsonic index, it might be quite worth while to give a few inoculations of T.R., so as to raise their index to normal or higher, for it has been found that even in healthy people the tuberculo-opsonic index rises rapidly after a dose of T.R. Of course the treatment might have to be repeated several times, but even then I think that it would be quite worth while if it procured immunity from the disease. In the *early* cases of pulmonary tuberculosis I do not think that there is much object in inoculating as practically all these patients do well with ordinary sanatorium treatment, though Trudeau seems to have found at the Adirondack Sanatorium that he gets a better percentage of "cures" in those cases which have been inoculated than in those which have not. So far I have not used inoculations in any of these cases and cannot therefore speak from experience. If, however, I found that an early case was not getting well with ordinary sanatorium methods I should certainly advise inoculations. In cases of *acute* pulmonary tuberculosis I do not consider that it would be advisable to inoculate, because if the index naturally fluctuates rapidly from day to day it is quite conceivable that—in spite of the utmost care in estimating the index—one might chance on a negative phase, which would only be increased by that due to the inoculation, and harm might be done. In these cases I think that our only chance lies in absolute rest and feeding as much as possible in the hope that the disease may be arrested as in the cases that I have mentioned before. Then later, when the lungs are quieter and the index has become steady, inoculations might do good and help towards completing the so-called cure.

In the ordinary sanatorium cases where the mischief is in a subacute state and where the patient does not seem to be making the progress that we can reasonably expect, I think that inoculations of tuberculin, controlled by the opsonic index, may do a considerable amount of good. In these cases there is probably an absence of stimuli to the immunising machinery and there is accordingly no corresponding production of antitoxins. If, now, by inoculating we give the necessary stimulus we should get a corresponding production of antitoxins accompanied by a rise in the opsonic index and improvement in the lung condition. The index does not, however, always respond, for in one case a fair amount of improvement was found in the lung condition without really much effect on the opsonic index. So far we have not had a large number of cases inoculated because we always first try what ordinary sanatorium methods will do, but if we find that the patient is not progressing satisfactorily we advise inoculations in the hope that the extra stimulus will help on to a "cure." Out of seven cases of this class that we have inoculated, one patient left after three inoculations before

there had been time to obtain any effect, three patients have left much improved, and three are still under treatment.

Of the three which have left much improved I will give brief details. The first patient had subacute mischief in the upper half of each lung of about one year's standing. We began inoculating him fairly early and when he left eight months later the disease had quite cleared up and there were only the signs of healed lung present. The mischief certainly disappeared in a more complete and rapid fashion than I remember to have seen with sanatorium treatment alone. After each inoculation there was a negative phase, followed by a considerable rise in the index—on one occasion to 2.1. At first, when we were having the indices estimated by Dr. R. H. Urwick, they were only done before and after each inoculation and hence there were recorded only sharp ups and downs, but later, when we were doing the estimation ourselves more frequently, we got more gradual fluctuations. At first we were using doses of $\frac{1}{10}$ of a milligramme (which Sir A. E. Wright at that time recommended), but later we used only $\frac{1}{100}$ of a milligramme, and though the index did not rise as high, still it remained up for a considerable time—in one case it did so for nearly two months. The last two estimations which were made three months after he left the sanatorium and had been carrying on treatment at home without any inoculations for four months show that the index has dropped below normal.

The second patient had considerable mischief in the left lung with a right lung collapsed by old pleural effusion and we did not begin inoculating until the lung condition seemed to have become stationary under treatment. After two or three inoculations he seemed to go ahead again and the lung condition improved considerably before he left, three months later. His index from being chiefly subnormal rose to above normal and kept almost entirely above it. It dropped again after he left.

In the case of the third patient, as in that of the preceding one, we noted that after a few inoculations the bacilli in the sputum had clumped, and if clumping is a sign that the bacilli are finding the conditions adverse to them it shows that the inoculations are undoubtedly doing good. This patient had been undergoing sanatorium treatment for some years and had a fair amount of chronic mischief in each lung. After the inoculations this condition improved considerably but his opsonic index made very little response to the inoculations and remained about constant, though very frequently estimated.

Of the three patients whom we are at present (November, 1906) inoculating the first had the whole of the right lung and half of the left affected with mischief in a subacute state, and as after six months' sanatorium treatment her progress—which had been very good—had apparently come to a standstill we advised her to try inoculations. Her index responds fairly well to small doses of tuberculin and the lung condition is again improving. The next patient had moderately acute mischief in the upper lobe of the left lung with some infiltration of the apex of the lower lobe. Since we began inoculating him a month ago the lung condition has improved and there are much less cough and expectoration. Both he and the last patient report also an improvement in the appetite since beginning inoculations. The last patient of this class had rather acute mischief in the left upper lobe, with a large cavity, some scattered mischief in the right lung, a small ulcer on her right vocal cord, a high temperature ranging from 101° to 103° F., a very feeble general condition, and a weight of only 4 stones 11 pounds. Sir A. E. Wright began inoculating her and then sent her on to us for sanatorium treatment. She responded readily to inoculations of $\frac{1}{100}$ of a milligramme of T.R. and her lung and throat condition had improved somewhat, but the great difficulty in her case was the poor general condition, combined with low weight and extremely small appetite. From her opsonic chart there appeared to be no auto-inoculation of tuberculin, for her index rose and fell regularly after each inoculation, and therefore I am inclined to think that her temperature was not due to the tubercle bacillus but possibly to staphylococcus or pneumococcus, both of which were found in her sputum.

We have had two cases of tuberculous glands. In the first the patient had had a slight attack of pulmonary tuberculosis but had got quite well. In December, 1905, he began to have acute abdominal pain, chiefly in the right side of the abdomen, and two irregular painful swellings could

be detected on palpation, one near the umbilicus and the other external and higher up. Owing to the severe pain, which I thought to be due to a local peritonitis, I kept him quiet in bed for nearly five months without much, if any, improvement, often having to use large doses of morphine to check the pain. Then I began inoculating him with a tubercle vaccine. After five inoculations he could walk a little, and after two or three more he could walk fairly well and he went home. He came back a little later with a return of pain which subsided after an inoculation or two, and a short time later he climbed Moel Famman (1800 feet) without more than temporary discomfort. He has now, except for a very few occasional attacks, been practically free from pain for a year, but has come back recently for a few inoculations to try to get rid of the pain altogether. I believe that he has had tuberculous mesenteric glands, causing a local peritonitis, and that the inoculations have caused the glands to decrease in size and to become much quieter and have also abolished the peritonitis, leaving only adhesions from which he occasionally gets pain. This patient also had a form of acne all over his back which no treatment seemed to clear up, but it all disappeared after a few of the T.R. inoculations however, possibly proving that it was tuberculous in origin.

In the second gland case there were tuberculous cervical glands in a patient who had been operated on for them about a year ago. When he came to us the glands were all round the angle and ramus of the inferior maxilla on the left side and he had an erratic high temperature. We began inoculating him after a month's rest in bed, and a month later the temperature had fallen considerably and the weight had gone up while the glands had decreased in size. Two months later the temperature had fallen quite to normal, the weight had increased about a stone, and the glands were much diminished. Then a sinus formed and a fair amount of discharge came away and several of the glands got much smaller. Since then they have continued to decrease with more inoculations, but the sinus has persisted and we are now using a staphylococcal vaccine and the amount of discharge is perhaps slightly less already.

Of course, inoculations of tuberculin will not cause absorption of chalky or caseous material, but I am sure that if these stages have not been reached they will cause absorption of much, if not all, of the inflammatory material of the glands, whilst probably rendering a subsequent operation smaller, easier, and more likely to heal perfectly, as Gray¹² of Aberdeen has already found.

We have one case of tuberculous laryngitis which is being inoculated and so far as the case has gone I think that the inoculations have done good, but it is too soon to speak with certainty yet. Apart from tuberculous cases we have had one case of farunculosis in which the boils disappeared after two inoculations of a staphylococcal vaccine, and in this case it is interesting to note that the staphylococcal index responded well to the inoculations whilst the tuberculous index remained stationary.

Before closing there are one or two points that I should like to mention with regard to the inoculations. At present we confine our inoculations to those subacute cases which do not seem to be progressing as satisfactorily as we could wish, but there is no reason why all cases, except perhaps acute ones, should not be so treated, and even the acute ones might be inoculated provided that very small doses were used so as to produce a very transitory negative phase. These acute cases are at present our most hopeless ones, and if we can get anything that may do them good I think that it will be worth trying. We always estimate the opsonic index several times before beginning to inoculate so as to make sure that there is no auto-inoculation, because one does not wish to add even a small negative phase to one already present from natural occurrences. Again, in order to avoid auto-inoculation from exercise we always rest our patients for one day before and two or three days after an inoculation. We usually start with a small dose, such as $\frac{1}{100}$ th of a milligramme or $\frac{1}{10}$ th of a milligramme of tuberculin, and it is wonderful what an effect such a dose has on the index besides being practically without any risk or negative phase.

Of course, in cases of pulmonary tuberculosis there is usually a mixed infection, and after, or while, using tuberculin it may be necessary to give inoculations of a staphylococcal or pneumococcal vaccine before the patient will get

well. Gray of Aberdeen noted this in connexion with cases of local tuberculosis, and he also found that patients who were subsequently operated upon healed more rapidly and perfectly and were less liable to sinus formation than those who were not previously inoculated.

Before beginning to inoculate it is necessary to make sure that the vaccine corresponds exactly to the micro-organism with which the patient is affected, and in most cases it is necessary to make a vaccine from a culture of the particular germ which is causing the disease. In the case of tubercle this is almost impossible owing to the difficulty of culture, but if it could be done the results might be even better. We have not yet had any untoward effects from inoculations, though on two occasions the temperature has risen afterwards for a day or two. The good effects are a lessening of activity—as shown by improvement in the physical signs and lessening of the amount of sputum—and improved appetite and increase of weight.

I am afraid that I have dealt with this great subject very imperfectly but it has proved a most difficult task to be brief and at the same time to say exactly the right thing to make myself clear. I have dealt almost entirely with the tuberculo-opsonic index, because it is the one with which I am best acquainted; but Sir A. E. Wright and others have proved that the principle of vaccine inoculation is available in many other germ diseases. The great drawback at present is the length of the processes which render the method difficult of general application, but to get the best results I feel sure that one must make use of the opsonic index and not give inoculations without any guide. Whether Sir A. E. Wright will add to his already brilliant researches and devise a shorter method of controlling the inoculations I cannot say, but there is no doubt in my own mind that by the present method he has made a most valuable addition to our available resources for combating disease.

Ruthin.

A REVIEW OF THE PRESENT MEANS OF COMBATING SLEEPING SICKNESS.

By ALLAN KINGHORN, M.B. TORONTO,

AND

JOHN L. TODD, B.A., M.D., O.M. MCGILL.

(From the Runcorn Research Laboratories of the Liverpool School of Tropical Medicine.)

THE recent public confirmation by Koch [1]* of the value of gland palpation and puncture in the diagnosis of human trypanosomiasis and of atoxyl in its treatment has once more attracted considerable interest to the existing means of combating sleeping sickness. In diseases of this type, like malaria, in which the specific parasite is carried from vertebrate host to vertebrate host by an invertebrate intermediary, prophylactic measures designed for the protection of the vertebrate host may be directed either against the parasite or against its transmitting agent. It is possible that *Trypanosoma gambiense* may be parasitic in other vertebrate hosts than man and that it may be transmitted by insects other than tsetse flies (*Glossina palpalis*), but so far as is at present known it occurs only in man and can be carried from man to man only by those insects. In practice efforts to check this disease will therefore be directed (1) against its transmitting agent—the flies—(a) by destroying them or (b) by preventing them from reaching and biting men; and (2) against the causative parasite—the trypanosome—(a) by the treatment of persons already infected and (b) by their isolation in order that they may not constitute foci of infection for other individuals.

(1 a).—Comparatively little is known of the bionomics of the tsetse flies and at present there seems to be no weak point in their life-cycle at which they may be easily destroyed. Their greatest weakness seems to lie in the fact that the females deposit only one living larva at a time, and this (*Glossina fuscus* [2]) only at intervals of from two to three days. The larva is placed on the ground, becomes a puparium almost immediately, and in from five to six weeks

* The figures within brackets occurring throughout this article refer to the bibliography at the end.

the fly hatches out [3]. It has been suggested that fly-infested areas should be frequently fired for the purpose of destroying the fly while it is at this stage. In this connexion it is important to note that *Glossina palpalis* has been reported to deposit its larvæ about the roots of banana trees [4].

(1 b).—It is certain that the existence of an area 300 yards in width, free from rank undergrowth or grass, around a residence will do a very great deal to keep it free from tsetse [1, 2, 5]. The flies prefer rank vegetation near water; native villages and European settlements should, therefore, be placed as far as possible from such localities or, if this is impossible, they should be kept clear of undergrowth. The use of wire gauze and netting—often advisable, particularly when travelling by canoe—will be matters for personal care.

(2 a).—Very, very many drugs have been used in the treatment of human trypanosomiasis. The one which, so far, has given the best results is that preparation of arsenic—"atoxyl"—first recommended by Thomas and Breinl [6]. Their work has recently been confirmed by Kopke, van Campenhout, Broden and Rodhain, and Koch, all of whom have had a certain amount of success in the treatment of patients [7]. Koch, in particular, warmly advocates its use. Trypanosomiasis is a very chronic disease. It is well known that persons, always considered healthy, may die from the disease after a residence of from seven to 10 years in a country where sleeping sickness does not exist. When this is remembered the question must arise whether the "cures" recently reported will prove to be permanent. A very marked improvement almost immediately follows the administration of atoxyl [8 (p. 60)], but the experiments on animals made by Thomas and Breinl conclusively show that in spite of continual treatment there is frequently a recurrence of the disease and that death may finally follow, just as in an untreated trypanosome infection. The disease has unfortunately taken this course in some of Kopke's patients [15]. In our opinion the exact value of "atoxyl" in sleeping sickness is still problematical. That it has a considerable beneficial effect is certain; to obtain the greatest benefit from its use it must be given continuously and regularly [8]. It is only by the careful work along these lines of observers who have an opportunity of treating cases of human trypanosomiasis and who are prepared to keep records of their patients for several years that it will eventually be possible to determine the exact therapeutic value of this drug in human trypanosomiasis. In the meantime, however, its use is certainly strongly indicated, together with the employment of every aid to the general building-up of the patient's system [8 (p. 51)].

(2 b).—The means by which infected persons are to be prevented from becoming dangerous to those who are still healthy will, of course, vary as the disease is endemic or not in the district under consideration. In some districts the percentage of infected persons is so large that attempts to segregate them would certainly fail. In such localities, as well as in slightly affected ones, every effort should be made to persuade the natives to place their villages in cleared areas as far as possible from tsetse flies.¹ It will occasionally be practicable to establish villages of treatment and detention in districts in which the disease has only recently appeared. Such villages should be situated in places free from tsetse flies. In them would be isolated all local cases of sleeping sickness, whether indigenous or introduced.

Considerable success is anticipated from the application of quarantine measures designed to arrest the spread of human trypanosomiasis by preventing the entrance of persons infected with the disease into districts where it does not already exist [8]. The epidemiology of sleeping sickness shows that, as a rule, it spreads but slowly from a given centre but that it may be rapidly carried from infected to uninfected districts by the advent of persons suffering from it. Now, the individual African does not travel long distances alone; long journeys are made in caravans either purely native or under the control of Europeans or Arabs. Traffic of this sort, whether for trading or labour purposes, is comparatively easily controlled; therefore, it will be possible to prevent infected natives travelling in this way from entering uninfected districts.

It is well known that persons infected with trypanosomes

may appear to be well and may work like healthy individuals. It was previously impossible to diagnose such cases, save by tedious examinations of their blood. Greig and Gray [9] showed that trypanosomes could easily be found in the juice aspirated with a hypodermic syringe from the enlarged lymph glands of such cases. This observation was confirmed in the Congo, and it was found that in practice every negro who has enlarged cervical glands must, other causes being absent, be considered to be a case of trypanosomiasis until the contrary can be proved [8, 10]. This conclusion is supported by the results of further work in Uganda [1, 11] and in Sierra Leone [12] and Central Africa (private communication). We have therefore an exceedingly simple method of detecting early cases of human trypanosomiasis which may be applied by almost any intelligent person. That it is an efficient method has been shown in the Congo [8] by the examination of over 6000 natives inhabiting both infected and uninfected districts.

The way in which the above diagnostic method is to be applied to the protection of threatened areas in which sleeping sickness is not yet endemic is briefly as follows. To prevent infected persons from entering such districts, posts of inspection, under the control of medical officers, are to be placed at suitable points on the main caravan routes and all travellers will be examined. To obtain the expulsion of imported cases already introduced it will be made an offence for any employer or director of labour in an uninfected district to have under his control any person with enlarged glands.² All suspected persons will be sent towards an infected district to the nearest post of inspection, where the resident medical officer will confirm the diagnosis and will send the patient to one of the villages of detention where the case will receive treatment. It is superfluous to say that these villages should only be established in districts where sleeping sickness is already endemic. The difficulties of enforcing such measures are doubtless enormous but they will at all events put a stop to the importation by Europeans or Arabs of negroes—labourers or soldiers and their women—suffering from trypanosomiasis into districts where the disease was previously unknown. Much of the spread of human trypanosomiasis in the Congo basin is certainly due to this factor [8].

Natives of many parts of Africa already know and realise that enlarged glands mean sleeping sickness [13]. Many tribes have the conception of quarantine since they isolate their sick, and, if the matter be properly handled, it will not be difficult, in the Congo Free State at least, to obtain the eager co-operation of some of the more intelligent chiefs, who know what the disease means, in applying a measure which promises to check the advance of sleeping sickness.

In conclusion, it must be insisted that even if a drug be found "specific for trypanosomiasis as quinine is for malaria," every other means of fighting the disease must still be employed—mosquito destruction and segregation are much-employed methods of public malarial prophylaxis. As has been already said, we have no means of destroying tsetse flies in large numbers. Therefore those who have the direction of affairs in Africa should, by enforcing quarantine and isolation measures, do all in their power to prevent the further spread of human trypanosomiasis. The need for such preventive measures is immediate and urgent, since it is only too apparent that the disease is rapidly spreading southwards. One of us published a few months ago in THE LANCET [14] a map taken from Memoir XVIII. of the Liverpool School of Tropical Medicine, which indicated the distribution of sleeping sickness in the Congo Free State in 1905. The disease now extends much further to the south. In the east the disease is actually endemic along the shores of Lake Tanganyika between about 4° and 7° South of the equator. Imported cases have been reported from Moliro, at the southern end of the lake, as well as from Kasenga, and from another point equally far south (10° 30') two degrees further west. In the west, in Portuguese West Africa, cases have been reported from equally far south.

Just at present new mining fields are being opened, and new railroads are being built in the south of the Congo Free State. Labourers will be brought to these works from considerable distances, and unless the greatest care be taken in their recruitment, their camps will become centres for the

¹ It must be remembered that a place cannot be said to be free from tsetse flies until after a careful search extending over a considerable period of time has been made [2].

² In the Congo Free State this is now an offence punishable by a fine of 200 francs with, in the case of an official of the Free State, such additional punishment as seems advisable.

dissemination of human trypanosomiasis in a district at present uninfected by that disease.³

PARATYPHOID FEVER IN THE TROPICS: CASES OF MIXED INFECTION.

PARATYPHOID FEVER AND MALARIA; PARATYPHOID FEVER
AND STAPHYLOCOCCÆMIA; PARATYPHOID FEVER AND
PNEUMOCOCCÆMIA; PARATYPHOID FEVER AND
TYPHOID FEVER.

By ALDO CASTELLANI, M.D. FLORENCE,

DIRECTOR OF THE CLINIC FOR TROPICAL DISEASES, COLOMBO.

As a small addition to our knowledge of the occurrence of paratyphoid fever in the tropics, it may be desirable to put on record the cases which I have observed in Ceylon, where the presence of the disease was hitherto not recognised. In the years 1904 and 1905 four cases came under my notice, and during the severe prevalence of typhoid fever in Colombo during the months of March, April, and May, 1906, I examined five other cases. Besides these nine cases of simple paratyphoid infection, I have met with four cases of mixed infection.

The cases of simple paratyphoid infection examined by me could not be clinically differentiated from typhoid fever, of which disease five presented all the classical symptoms: gradual onset, typical temperature chart, and enlargement of the spleen. In the remaining cases the disease began suddenly with shivering and rheumatoid pains, the temperature rising very high immediately. In the tropics, however, typhoid fever may not rarely present these atypical symptoms. The Widal reaction performed several times was negative in all. The stools and urine were investigated repeatedly, using MacConkey's media for plating. The bacillus typhosus was never isolated. In five cases a bacillus was isolated with the characters of the bacillus paratyphosus A (Brian and Kayser): actively motile; no liquefaction of gelatine, very slight production of indol; milk acid, but unclotted; acid and gas in dextrose, levulose, maltose, and mannite; no change in saccharose and lactose. In four cases a bacillus was grown with the same cultural characters, the only difference being that it produced a little more indol, and that in litmus milk it induced a slight initial acidity soon followed by a well-defined and permanent alkalinity (bacillus paratyphosus B, Shotmüller). The two types were further determined by agglutination tests, using also some sera of known origin. All the cases ran a mild course with the exception of one which ended fatally. This case has some interest from a pathological aspect. It is generally admitted (Lucksh, Wells, Scott) that in paratyphoid fever there is, as a rule, absence of intestinal ulceration. In my case, however, the lower part of the ileum showed several ulcerations absolutely identical with typhoid ulcers. The mesenteric glands were much enlarged.

and spleen were examined bacteriologically. The bacillus typhosus was not found. The bacillus paratyphosus A was found to be present in pure culture in the spleen and mesenteric glands; in the ulcers it was mixed with the bacillus coli and other organisms.

CASE 1. Paratyphoid fever and malaria.—The patient was a man, aged 24 years. There was no previous history of malaria or of any other illness. In April, 1905, a few days after he had returned from a malarial district, where he had only been for a short time, he was taken suddenly ill with severe shivering, the temperature rising to 104.2° F. The blood contained numerous parasites of benign tertian. On the second day the temperature was 99.4° in the morning and 101° in the evening; on the third day the patient had shivering again, and the temperature rose to 103.6°. On the fourth day the temperature was 101° in the morning and 102.2° in the evening. On the fifth day it was 100.8° in the morning and 101.4° in the evening. By that time the malaria parasites had completely disappeared from the blood. The temperature, however, continued for nine days more, varying from 99° to 102°. From the fifteenth to the twentieth day it varied from 98.6° to 100.8°. The spleen could never be palpated; there were no roseola spots. There was marked constipation. The patient received 30 grains of eucaline daily during the first week and 15 grains afterwards. On the seventh day of the disease the stools were examined bacteriologically and a bacillus paratyphosus B (Shotmüller) was grown. On the tenth day the same organism was grown from the urine. The blood of the patient agglutinated this germ in a dilution of 1 in 500, while it never influenced the typhoid bacillus. The patient remained in good health for three months, when he again had an attack of fever, the temperature rising to 103.6°; the blood contained some parasites of benign tertian. Eucaline was given. On the third day the temperature rose to 99.4° only and afterwards remained normal. The stools were examined, but only bacilli coli were grown. This second attack was simply of malarial origin.

CASE 2. Paratyphoid fever and staphylococciemia.—The patient was a young German, 26 years of age. There was no history of any disease of importance. He had been for three years in Ceylon and had lived in the bungalow where the case of paratyphoid fever and typhoid fever, described later, occurred. At the end of June, 1906, he had complained of vague malaise and headache. He had pyrexia which never rose above 102.2° F., of rather irregular type. Widal's reaction was negative. The blood was investigated bacteriologically, using my dilution method. A staphylococcus albus was grown. From the stools a bacillus paratyphosus A (Brian and Kayser) was isolated. The blood agglutinated this germ in a dilution of 1 in 800. About a week after the staphylococcus had been grown from the blood the patient developed numerous boils all over the body, some of them rather large. The pus of these boils was examined bacteriologically and the staphylococcus pyogenes albus and aureus were grown. The fever lasted altogether 14 days.

CASE 3.—Paratyphoid fever and pneumococciemia.—The patient was a married woman with nothing of importance in her history. In April, 1905, shortly after having returned to Colombo from the hills, she complained suddenly of sore-throat and of difficulty in swallowing; she had shivering and the temperature rose in a few hours to 103.4° F. When I saw her both tonsils were covered with whitish exudation, the submaxillary glands being enlarged. The lungs were clear and nothing abnormal was to be noticed at the examination of the heart. The spleen was not enlarged. There was a trace of albumin in the urine. Two swabs were taken and were examined bacteriologically, films and cultures being made. In the films extremely numerous diplococci not decolourised by Gram's method were present. Culturally, the search for the diphtheria bacillus was negative; a diplococcus was grown with all the characters of the pneumococcus. The throat symptoms disappeared in four days, but the fever, varying from 100° to 102.4°, did not leave the patient till much later. Her blood was then examined for Widal's reaction with negative results. The blood was also examined for bacteria, using the dilution method. A coccus with the characteristics of the pneumococcus was grown. As at that time a slight diarrhoea had set in the stools were examined bacteriologically; a paratyphoid bacillus of the type B was isolated. The blood agglutinated the bacillus, using a dilution of 1 in 300. The blood had for the pneumococcus grown fr

³ Private information indicates the great probability that labourers from the thickly populated but infected areas to the south of Lusambo and from Cabinda will go south to work on the railroads. If such an unfortunate occurrence is to be prevented action must be immediate.

Five days later the bacteriological investigation of the blood was repeated, the patient having no objection. Four cubic centimetres of blood were distributed in five flasks, each containing 300 cubic centimetres of pepton-broth. Two of the flasks remained sterile; three became turbid; of these, two contained in pure culture a motile bacillus which further investigation proved to be identical with the one isolated from the stools—viz., the bacillus paratyphosus B. The third flask contained in pure culture a coccus with the characters of the pneumococcus. This case is very similar to those described by Baduel of mixed infection of pneumococcus and bacillus typhosus.

CASE 4. *Paratyphoid fever and typhoid fever.*—The patient was a man, aged 36 years, of German nationality. He had lived in Ceylon for 15 years. There had been no previous illness of importance. At the end of May, 1906, he began to complain of lassitude, headache, and loss of appetite. I saw him on the 28th. His tongue was fairly clean and the spleen was slightly enlarged; there were no roseola spots. On the following day I examined his blood for Widal's reaction with negative results; having, however, little doubt that it was a case of typhoid fever, I had him removed to a nursing home. The course of the fever is shown in the accompanying temperature chart. The disproportion between the pulse-rate and the temperature will be noticed at once; even when after three weeks the temperature dropped to nearly normal, the pulse remained very frequent. In my experience this sign renders the prognosis much less favourable. The patient had two very serious intestinal hemorrhages in the third week. He died in coma after a prolonged illness.

The first bacteriological examination was made on the seventh day of the disease. The stools were collected in a large sterile Petri dish and plated, using the MacConkey medium. All the white colonies which developed were further investigated. The bacillus typhosus and the bacillus paratyphosus B were isolated. The examination of the faeces was repeated twice—once in the third week and once three days before death. The result was the same. On one occasion two strains of the bacillus typhosus were grown: one rendered litmus milk alkaline after 36 hours; the other rendered the medium strongly acid permanently; as regards other culture characters and agglutination tests both strains were identical. The urine was examined bacteriologically twice, on the twelfth and fiftieth days of the illness; on both occasions the bacillus paratyphosus B was grown.

Agglutination tests of the blood gave the following results. On the seventh day of the disease: bacillus typhosus, dilution 1 in 10 negative; bacillus paratyphosus B, dilution 1 in 10 negative. On the seventeenth day of the disease: bacillus typhosus, agglutination limit 200; bacillus paratyphosus B, agglutination limit 300. On the forty-sixth day of the disease: bacillus typhosus, agglutination limit 800; bacillus paratyphosus B, agglutination limit 1000.

The results of the absorption tests carried out according to my method¹ on the forty-sixth day of the illness are collected in the following table:—

	Agglutination limits before absorption.	Agglutination limits after absorption of the typhoid agglutinins.	Agglutination limits after absorption of the paratyphoid agglutinins.
Bacillus typhosus	800	nfl.	800
Bacillus para-typhosus B ...	1000	1000	nfl.

The result of the absorption test clearly shows that the blood contained *specific* agglutinins for each bacterium and excludes the possibility of the case being one of typhoid fever with the presence of the bacillus paratyphosus B as a mere saprophyte. Both germs had part in the etiology of the infection and the case is to be considered, therefore, a mixed infection of paratyphoid and typhoid fevers similar to the cases recorded in Europe by Wagner and Conradi, Boycott and Gachtgens.

Conclusions.—1. Ceylon must be included among the countries where paratyphoid fever is endemic; both types

¹ The technique to be followed in performing the test may be found in my original paper (Zeitschrift für Hygiene, 1902, p. 1), or in the publications of Kolle and Heich (Die experimentelle Bakteriologie, 1905), or Boycott (Journal of Hygiene, 1905), &c.

of the disease, paratyphoid A (Brian and Kayser) and paratyphoid B (Shotmüller), are met with. 2. The disease is clinically indistinguishable from typhoid fever, though generally it runs a milder course. 3. In the case of paratyphoid A, which ended fatally, intestinal ulcers were found identical with typhoid ulcerations. 4. Cases of mixed infection are apparently not rare.

A CASE OF TRANSPOSITION OF THE VISCERA.

By FRANÇOIS E. LARKINS, M.B., CH.B. EDIN., D.P.H.,
LATE RESIDENT MEDICAL OFFICER, HOSPITAL FOR SICK CHILDREN,
NEWCASTLE-ON-TYNE.

SINCE 1643 only about 200 cases of this interesting condition have been reported, so that the following case may be said to possess the virtue of comparative rarity.

The patient, an infant, aged 12 months, was admitted to the Hospital for Sick Children, Newcastle-on-Tyne, under the care of Mr. T. G. Ouston, suffering from a mastoiditis which proved to be of a chronic tuberculous type and associated with other tuberculous lesions in one leg and both arms. The condition of the child prevented any treatment beyond temporising and death ensued later from tuberculous meningitis.

At the post-mortem examination the following interesting condition was able to be investigated. The heart, of about normal size, lay in the centre inclining to the right, with its apex one inch from the middle line. The right ventricle had hypertrophied walls, simulating those of an ordinary left ventricle. The left ventricle was smaller than an ordinary right ventricle. The organ being kept for hardening as a permanent specimen was therefore not opened so that the condition of the interior was not ascertained. As regards the lungs, that on the right side possessed two lobes, the anterior border having the usual outline of the left. The lung on the left side, with three well-marked lobes, had an uninterrupted anterior border. The oesophagus lay to the left of the aorta in the posterior mediastinum till near the diaphragm, where it crossed that vessel and was then situated to the right of the middle line. The stomach occupied the right hypochondrium and the duodenum proceeding to the left and being reflected round the head of the pancreas turned back towards the right. The vermiform appendix was situated in the left iliac fossa, the ascending colon necessarily being on the left side; the descending colon on the right; the sigmoid flexure in the right iliac fossa, and the rectum commencing from the right side. The foramen of Winslow was on the left side. The liver was normal but was situated on the left side. The spleen was also normal but on the right side. The pancreas was reversed, with its head on the left side and its tail on the right. The left crus of the diaphragm was longer than the right and inserted lower. The kidneys were both normal but the right one was higher than the left. The left suprarenal gland was triangular in shape and the right one was filiform; both were about normal in size for the age of the subject. The arteries and veins showed complete transposition in every detail. The aorta arose from the right ventricle, arched round to the right, and extended down the right side of the vertebral column. The innominate artery was on the left side, having the left recurrent laryngeal nerve reflected round it. On the right side was a common carotid and subclavian artery. The recurrent laryngeal nerve on the right side was unfortunately cut, so that it could not be traced. The long renal artery and intercostals were, of course, on the left side. The pulmonary artery came off the left ventricle and gave three branches to the left lung and two to the right. The veins were correspondingly transposed. The right innominate vein crossed over to the left side where, joining the short left innominate, it formed the superior vena cava, which entered the left auricle. The right renal vein was the longer of the two and into it

emptied the right spermatic vein. The left spermatic vein entered the inferior vena cava at the point just below the junction with it of the left renal vein. The thoracic duct was on the right side.

On consulting the literature available on the subject all the cases published up to 1895 amounted to 190, which number was collected by Pic. The earliest reported case was in 1643, occurring at Rome. Complete transposition is the rule, and usually with no other malformations present. Males figure more largely than females in the cases reported. The unusual condition does not in any way inconvenience those affected, few of them being aware of its existence.

The causes of *situs inversus* I do not intend to go into but would refer anyone who is interested in the subject to a very excellent *résumé* of the opinions of different authorities in an article by Arnell in the *American Journal of the Medical Sciences*, Vol. OXXIV., 1902.

I should like to take this opportunity of thanking both Mr. Ouston and Dr. R. A. Bolam for permitting me to publish the case.

Leith.

THE VISUAL EFFICIENCY OF THE UN-CORRECTED MYOPE.

By J. HERBERT PARSONS, D.Sc. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, ROYAL LONDON (MOORFIELDS) OPHTHALMIC HOS-
PITAL; ASSISTANT OPHTHALMIC SURGEON, UNIVERSITY COLLEGE
HOSPITAL; LECTURER ON PHYSIOLOGICAL OPTICS,
UNIVERSITY COLLEGE, LONDON.

VISUAL acuity, in the generally accepted sense of the term—i.e., the acuity of central or foveal vision—is only one out of many factors which must be taken into consideration in determining the visual efficiency of a given patient, meaning by the latter term the efficiency of the individual from the point of view of sight to perform the various acts and functions of life. In the majority of cases visual acuity is the most important factor, but circumstances may be such as to relegate it to an inferior position. Of the well-nigh innumerable factors which play a part in visual efficiency, many, and amongst them visual acuity, must be regarded from two standpoints, the physical or optical and the physiological. Much misapprehension and extremely erroneous deductions have arisen from ignoring this essential fact. The optical problem itself is much more complex than is often suspected and seeing that it is fundamental, being conditional to many factors in the physiological problem, it is the more necessary that it should be rightly apprehended. It will be well, therefore, to discuss the visual efficiency of the uncorrected myope by the enumeration and valuation of the various physical or optical and physiological (and pathological) conditions of his vision.

Taking as an example a person with myopia of 9 D. the optical conditions will vary according to the nature of the myopia. It is usual to regard such myopia as being invariably due to elongation of the eye, axial myopia, as it is called. Though stretching of the posterior segment of the globe is undoubtedly the most prominent feature in these cases it is probably more frequently than is generally thought, accompanied by some flattening of the cornea, slight displacement of the lens, and possibly some abnormality in the curvature of the lens surfaces. The condition may, indeed, be a complicated one anatomically, resulting in a combination of axial myopia and of curvature myopia, the latter itself made up of complex components. We are at once brought face to face with the intricacy of the problem and the danger of theoretical deductions, for the optical conditions of axial and curvature myopia—to leave out of the question the possible displacement of the lens—are quite different.

Bearing in mind the possibility of error from this source we will consider that the myopia is purely axial. With an axial myopia of 9 D. the posterior wall of the globe is stretched, so that the retina is displaced backwards to the extent of three millimetres as compared with the normal emmetropic eye—i.e., the antero-posterior diameter of the eye measured from the surface of the cornea is 26 millimetres instead of 23 millimetres. Under the conditions which have been accepted the anterior segment of the eye-ball is normal in every respect. Consequently, parallel rays of light falling upon the cornea

23 millimetres behind it. They will then cross and continue to diverge from each other until they fall upon the retina three millimetres farther back. Hence the image of a distant object, more than six metres away for example, which would have been a sharp inverted image at 23 millimetres, is now blurred owing to the divergence of the rays. Thus far the conditions may be fairly well simulated by a photographic camera. If a distant object is photographed on a sensitised plate situated slightly behind the position of the principal focus of the lens an inverted blurred image results, which is not unlike the retinal image formed in an axially myopic eye. It is by no means justifiable to regard this as other than a very imperfect analogy. It must be remembered that the conditions of magnification are totally different, all the refracting media are different, and the screen is flat instead of being approximately spherical.

Two factors enter into the consideration of the amount of blurring in the myopic eye—viz., the degree of myopia or excess of the axial measurement of the eye over 23 millimetres and the size of the pupil. The image of a spot of light is a diffusion circle, the diameter of which varies with the diameter of the pupil in accordance with the rules which obtain in all optical instruments. In the myope the pupils are usually larger than in emmetropic eyes. Hence the blurring of the image is greater than would be the case with a small pupil. On the other hand, it must be borne in mind that the relative increase in size of the pupils is diminished as compared with the normal eye when the illumination is decreased, consequently there is little increase of blurring due to this cause under feeble illumination. The size of the pupils varies in different myopes; if they are very small, e.g., under eserine, the circle of diffusion becomes very small, so that clear vision may be obtained irrespective of the degree of myopia; of course in these circumstances the image is very feebly illuminated. It is this condition which is induced artificially by the dangerous method of improving the vision of the short-sighted by massage—"without the use of glasses." The amount of massage necessary to attain this end involves risks to the eye which no responsible practitioner would venture to run; moreover, the effect is transient. Stenopæic vision having the same effect as constriction of the pupil, can, however, be attained by other means. By screwing up the lids their margins become the "pupil of entry" of the optical system, the image of a point of light being transformed into a sharply defined line. In this manner distant vision may be very markedly improved, a fact known from time immemorial, accounting, in fact, for the term "myopia." This method of improving vision without the use of correcting glasses is of prime importance in estimating the visual efficiency of an uncorrected myope.

The distance of objects from the eye of course greatly influences the retinal image. Thus, in the emmetropic eye without accommodation the size of the circles of diffusion increases directly as the object is brought closer; the same occurs to a less degree in the hypermetropic eye. In the myopic eye the increase is more rapid within the far point of the eye; at the far point a clear image is formed upon the retina. The effect due to this cause is, however, much modified as regards visual efficiency by the increased size of the image. In all cases as the object is approached the size of the retinal image increases and this may more than counteract the want of clearness due to imperfect focussing. Hence young patients with a high degree of hypermetropia often hold their books very close to the eyes, like myopes, in the same manner and for the same reason that people with corneal nebulæ do.

It is necessary to point out that with a constant size of pupil the luminosity of the retinal image is unaffected by approaching the object nearer to the eye, since the increase in the amount of light according to the square of the distance is spread over an area which is increased according to the square of the radius of the circle of diffusion. This rule does not apply to punctate images; consequently the more accurately the image is focussed upon the retina the brighter it will be. The large pupils of myopes expose the less accurately curved peripheral portions of the cornea and lens, thereby producing a certain amount of aberration which further tends to distort the image. The difference produced by this cause on diminishing the illumination will be less than in the emmetropic owing to the relatively greater dilatation of the pupils in the latter in these circumstances. It is unnecessary to discuss the effects of spherical and chromatic aberration here.

The physical factors which have been considered can be

estimated with mathematical accuracy if the requisite data are known. Enough has been said, however, to show that the conditions are so variable even in eyes with the same degree of myopia that only a very limited amount of accuracy is possible in the absence of exhaustive investigation of the individual patient. This is true to a much greater extent of the physiological factors. Setting aside absolutely pathological features which are so common in cases of high myopia—e.g., dense vitreous opacities, patches of choroidal atrophy, macular defects, &c.—there are yet changes in the myopic eye which seriously interfere with a valid appreciation of its probable visual efficiency. Most of these changes militate against visual efficiency, though some may even be favourable in certain circumstances. It is a fact that in high myopia the visual acuity may be less than normal with the most perfect optical correction, and that, too, apart from obvious changes in the media or fundus. This is seldom the case in myopia of moderate degree, e.g., up to 9 D. or 10 D. In myopia of more than 6 D. the field of vision not unfrequently is somewhat contracted for white and red. It is noteworthy here that it is the more luminous parts of the spectrum which are most involved, and this may account for the fact that many myopes seem to see better relatively even than emmetropes in a dull light, a most important consideration in estimating their visual efficiency under such conditions.

Over and above the factors already mentioned there is a psychological factor which is quite individual in its manifestations and in no small degree influences the patient's capabilities. The myope is usually of a studious turn of mind. Whether this be cause or effect in the moderate degrees of myopia need not be argued here. There is little doubt that in the higher degrees, which often begin early and increase rapidly, the dimming of the outer world tends to concentrate attention upon near objects and fosters introspection. How far this tendency will be cultivated depends largely upon the mental capacity of the individual and has nothing to do with the physical and physiological concomitants of myopia *per se*. In the lower classes, amongst whom the very high degrees of myopia are as common as amongst the studious, it has little or no effect, and it is astonishing how slightly these people seem to be inconvenienced in their daily life by their defect. It is by no means uncommon to find patients in a large out-patient clinic who have reached adult life, have very high degrees of myopia, and have never sought advice before. I have known patients with 18 D. or 20 D. of myopia who have never been corrected, yet have walked about in the crowded thoroughfares of the city and East London with impunity and apparently little difficulty. Not only so, but they have rejected any correction whatever, in spite of manifest improvement in central vision when tested with glasses. They have become so accustomed to their large faintly illuminated retinal images that they are hopelessly at sea with the relatively sharp, bright images which the glasses produce. This is the most important, though not the only, reason why very high myopes almost invariably prefer a considerably lower correction than the actual amount of their myopia would indicate.

There are other less potent factors which have not been considered. Enough has been mentioned to show how fallible must be any deduction as to the visual efficiency of any given myope in the absence of a thorough and exhaustive examination of the individual himself.

Wimpole-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF PRIMARY CHANCRE IN THE NOSTRIL.

BY ASLETT BALDWIN, F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON TO THE WEST LONDON HOSPITAL.

THE patient, a married woman, aged 26 years, went to the West London Hospital complaining of great pain and swelling in her face. She looked, and said she felt, extremely ill. The orifice of the right nostril was much larger than that of the left. About three-quarters of an inch up the nostril a slough was visible. When this was

removed a red, livid mass was laid bare which quite occluded the passage. The right side of the nose, the right cheek, the right side of the lips (especially the upper), and the glands beneath the right side of the jaw were very much swollen. The swelling of the parts caused epiphora. There was a well-marked secondary rash on the body.

Five months previously the patient's mother, aged 55 years, who lives in a neighbouring house, developed a typical specific throat. This was followed by an intense secondary rash, which has now (July, 1906) somewhat faded but is still well marked on the face. There is also iritis present in the right eye. Nine months previously the granddaughter of the patient's mother, aged 11 years, who lives with her, had a specific throat and rash. She now (July, 1906) shows no sign of the disease. As far as can be ascertained these two last patients showed no primary sore.

The sequence of events was, the granddaughter, aged 11 years, caught the disease first; how, we cannot find out. Her grandmother caught it from her; and finally, my patient caught it from the latter. Although she does not live in the same house she was often in and out of it and frequently took her meals there.

As cases of primary chancre in the nostril are very rare I thought this worth publication. The series shows the importance of warning patients who have contracted syphilis against the danger of infection of other people. It is a matter which I know is very often neglected and ought never to be omitted. All three patients were shown by my friend and colleague, Dr. H. J. Davis, at the Laryngological Society of London.

Manchester square, W.

NOTE ON A CASE OF HÆMATURIA DUE TO SALICYLATE OF SODIUM.

By J. D. MARSHALL, M.B. VICT., M.R.C.S. ENG.,
HOUSE PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

THE patient, a girl, aged ten years, was admitted on Oct. 25th, 1906, to Dr. H. D. Rolleston's ward in the Victoria Hospital for Children. She had been suffering from acute articular rheumatism for three days previously to that on which she was admitted; this was the first attack of rheumatic fever and the only illness that she had previously suffered from was measles when an infant. There was a family history of rheumatism; her father frequently had rheumatic attacks and her brother was a patient at this hospital in November, 1905, suffering from rheumatic fever and chorea. The usual symptoms of acute articular rheumatism were present; the ankles, the knees, and the hip-joints were painful and the skin over the right ankle was reddened. Endocarditis was also present, probably quite recent. The heart was very slightly enlarged. The temperature was 101.2° F. and the pulse was 120 per minute. A purgative was given and then 15 grains of sodium salicylate with double that amount of sodium bicarbonate made up with chloroform water every four hours; this was given for four days, when the child became delirious and vomited twice. The hallucinations were not unlike those of delirium tremens. The salicylate was at once withdrawn and the delirium then very quickly passed off. On the fourth day after admission the temperature, pulse, and respirations were normal.

On Nov. 8th the patient again complained of pains in the joints and salicylates were again given (seven grains in water three times a day). After taking this for two days she again vomited. There was no delirium but the urine contained blood in sufficient amount to give it quite a deep red colour; previously to this the urine had contained neither albumin nor blood. She also complained of severe pain along the left iliac crest and for about one inch above and below it; there was also much tenderness on palpation in the left renal region. No pain at all was caused by movement of the left hip-joint. Salicylates were discontinued on the 11th. The quantity of blood in the urine rapidly diminished in amount and on the 15th the urine was clear and contained neither blood nor albumin; the pain had also disappeared. This pain, which extended from the left loin to the left groin and was very marked along the anterior part of the iliac crest, in addition to hæmaturia and vomiting, presented symptoms not unlike those of renal calculus, but as the patient had never had similar symptoms previously, and the fact that all disappeared when salicylate of sodium was withheld, would

suggest that drug as the cause. The pain was in all probability purely a "referred pain" from the kidney, as all along the painful part the skin was very hyperæsthetic, quite as much pain being caused by lightly pinching up the skin as by moderately heavy pressure. It is remarkable, however, that all the signs and symptoms of kidney irritation were confined to one side.

The patient evidently cannot tolerate salicylates, as first these caused delirium and vomiting, and on the second administration hæmaturia, vomiting, and pain. She has remained quite free from pain since Nov. 15th. She now (January) has a mitral systolic and mid-diastolic murmur; the systolic murmur is conducted to the axilla and back. Hæmaturia due to ordinary medicinal doses of salicylates has not, I believe, been frequently seen, or at least recorded, by English observers. It has occurred in salicylism, but probably rarely with such a small dose as that given to this patient.

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamprimum et morborum et dissectionum historia, tum aliorum tum proprias collectiones habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

ANCOATS HOSPITAL, MANCHESTER.

TWO CASES OF LARGE VENTRAL HERNIA.

(Under the care of Mr. E. STANNORE BISHOP.)

CASE 1.—The patient, a female, aged 37 years, was admitted to hospital on July 30th, 1906. Six years previously to admission she had had ventrofixation performed for prolapse of the uterus. She was a large, loosely built, flabby woman, with great development of subcutaneous adipose tissue. This operation had been followed by supuration of the abdominal wound which necessitated her retention in hospital for over a month. The following year she had undergone an operation for hernia at the site of the wound which was unsuccessful; this was evident before her discharge and ever since she had worn a belt which, however, failed entirely to support the hernia. On her admission one-half of the abdominal contents appeared to lie immediately beneath the skin which formed an immense pouch over the front of the lower half of the abdomen. It was impossible to reduce the hernia completely; perhaps one-third of the whole could be returned, but the remainder was evidently adherent to the interior of the sac and could not be reduced; the opening was a wide one and when part of the extruded gut had been replaced it easily admitted all the four fingers of the hand. At its widest diameter when full the sac measured 23 inches transversely by 13 inches vertically; the opening measured at the time of operation three and a half inches from side to side, and extended from the pubes to two inches below the umbilicus. On several occasions during the six years of its existence the patient had suffered from pain in the mass and vomiting; she had also been the subject of "windy spasms." The action of the bowels had been irregular and she was totally unfitted for any work.

At the operation on August 9th, 1906, a curious state of things was found: the skin over the protrusion was brown and wrinkled; a large elliptical piece was removed; the sac thus laid open was lined throughout with peritoneum; adherent to this at many points was a very fat omentum in which were several harder, encapsuled lipomata; a great amount was tied off and removed; its weight after removal was two pounds three ounces. The intestines themselves were not adherent; after the removal of the omentum they could all be reduced into the abdomen proper. The opening between the two cavities precisely resembled the opening into the true pelvis, so much so that a bystander suggested that the sutures had been passed through the edges of the psoas muscles and that it would be impossible to bring them together. The peritoneum covering one edge was divided so as to expose the fibrous lamina of the rectus sheath below; that on the opposite side was left untouched.

Strong iodine catgut was used in mattress stitches, and still further to strengthen the line of union a second layer was superposed upon the first. When the opening was closed a large cavity remained, the subcutaneous fat having been opened up as far as the anterior superior iliac spine on the right; this cavity was lined throughout by peritoneum; no attempt was made to remove this, but a drainage-tube was brought through the side at its lowest point and the large skin incision closed. There were some sickness lasting for a few hours and for a day or two some difficulty in breathing, due probably to the use of ether in anaesthetising, but all this rapidly subsided and her recovery was complete. She left the hospital well and with the long wound perfectly healed on Sept. 7th.

CASE 2.—The patient, a male, aged 65 years, was admitted to hospital on May 24th, 1906. In the year 1900 this man suffered from an umbilical hernia; this was operated upon in June of that year and the operation was followed by suppurative. Such an occurrence is always in my experience followed by relapse; it was so in this case. Two years later he returned to the hospital with a small ventral hernia to the right of the scar; he had also at this time a fairly large scrotal hernia, the contents of which were irreducible, being apparently adherent to the sac wall. The scrotal hernia, about which he had not previously complained, he now declared had been present for 20 years; its length from the external ring to the lowest point of the scrotum was 11 inches; its circumference 20 inches. The skin over it was pigmented but not thickened. On March 6th, 1902, the ventral hernia was dissected out; there were two medium-sized sacs with fascial openings, each of the size of a shilling, lying side by side in the line of the scar with a narrow fascial bridge between; after removal of the peritoneal sacs and closure of their openings, the fascia on the left was cleaned from fat for a quarter of an inch and then the peritoneo-fascial layer on the right side was brought over this and united to it by mattress sutures; the skin was then united over all. In 13 days the external sutures were removed; primary union had taken place. Six days later the scrotal hernia was operated upon; the scrotum contained large intestine which was closely adherent to the sac wall. After reduction the opening in the abdominal wall extended the whole length of the inguinal canal; the peritoneal sac was twisted, ligatured, its excess cut away, and the stump carried upwards to a point one inch higher up on the interior of the abdominal wall and fixed there; then the conjoined tendon was drawn down to Poupart's ligament and united to it by several silk mattress sutures. A drainage-tube was drawn through an opening made at the lowest point of the scrotum and another was placed at the upper and outer angle of the inguinal wound; the skin wound was then closed and sealed with celloidin. There was a large amount of ecchymosis of the scrotal tissues and this broke down later. The deeper union remained firm, but the interior of the scrotum sloughed, requiring reopening throughout. The testis on this side necrosed and was removed. Ultimately two months after the operation the whole was soundly healed.

The patient returned to hospital on May 20th, 1906, with a moderate-sized ventral hernia in the line of the old ventral scar; this, he said, had shown itself within two or three weeks after leaving the hospital and had been gradually increasing since. A double opening was found in the muscular wall; these openings were each of about the size of a five-shilling piece and were separated by a strand of fibrous tissue; this was divided and the two openings were thrown into one. The cavities were filled by non-adherent small intestine which was easily reduced. The man was very stout and the tension of the muscular wall was great. It was evident that an endeavour to bring the edges of the opening together laterally would fail or, if it were possible, that they could not be made to overlap; the tension upon the sutures would be such that they would almost certainly cut out and the hernia return worse than before. There was some enteroptosis and it was thought that approximation of the edges from below upwards would not only be much easier, since the sutures so applied would not have to counteract the lateral pull of the oblique and transversales muscles, but to improve the tendency to falling forward and downward of the abdominal contents. The sutures were accordingly introduced in this manner with the best results; not only was a firm and extensive union obtained, but the abdominal wall lost its pendulous appearance and the man himself was much more comfortable. The wound was completely healed

by the tenth day and there have been no signs of relapse; on putting the abdominal muscles into action the scar retracts firmly.

Remarks by Mr. STANMORE BISHOP.—The method of closing a ventral hernia detailed above may or may not be original; it is probable that it is not, but I have not seen it previously described; many of the cases which have come under my own observation have occurred in stout persons in whom the intra-abdominal tension has been great; the endeavour to bring the muscular walls together from side to side is in such cases resisted not only by the contraction of the lateral muscles but by the shortening which always takes place in muscles which have been accustomed to symmetrical resistance as the obliques and transversales are when that resistance no longer exists; if the attempt to bring them together succeeds there ensues for such patients, after their recovery from the anaesthetic, a period of much discomfort; I have seen such patients strain violently for some days; I have often thought also that sickness and retching were much more marked and it seems probable that it must require some time for the stomach and intestines to become accustomed to the decreased space at their command; in this and in another case of which I have notes, treated by closing the opening by sutures applied from below upwards, these symptoms were conspicuous by their absence, the resulting scar, not being dragged upon during the plastic stage, is also much less likely to yield again and therefore relapses are not so much to be feared. In both cases a pendulous abdomen coexisted; the effect in lifting up the lower segment was markedly beneficial.

The first case is reported because it is the largest ventral hernia I have ever seen; at the operation half the abdominal contents were outside the true abdominal wall.

BRADFORD ROYAL INFIRMARY.

TWO CASES OF PURPURA HÆMORRHAGICA, ONE WITH A PECULIAR RETINAL CONDITION; AND A CASE OF RANT'S DISEASE TREATED BY THE X RAYS.

(Under the care of Dr. R. H. CROWLEY, Dr. R. HONEYBURN, and Dr. H. J. CAMPBELL.)

FOR the notes of the cases we are indebted to Dr. A. W. Falconer, late house physician.

CASE 1.—The patient, a female, aged 22 years, was admitted into the Bradford Royal Infirmary under the care of Dr. R. H. Crowley on April 3rd, 1906. Three weeks before admission she began to have pain in her joints and muscles. She attended as an out-patient and thought that she was getting better until the day of admission when she had violent epistaxis lasting the whole day, which was only stopped by plugging. She had no abdominal pain and her bowels were regular. On admission the temperature was 102.6° F., the pulse was 120, and the respirations were 28. The patient was a fairly nourished but intensely anæmic girl, the mucous membranes being almost colourless. There were two or three small glands of about the size of peas in the left inguinal region and one or two in the left axilla. There was no rash. A hæmic bruit could be heard at the apex; nil in lungs. The liver and splenic dulness were normal. The abdomen was slightly full; there was no tenderness. The optic discs were very pale and the vessels were small. There were no hæmorrhages. Blood examination showed: hæmoglobin, 20 per cent.; white cells, 12,500 per cubic millimetre; and red cells, 1,093,000 per cubic millimetre (see table). On the 5th there had been considerable hæmorrhage from the gums round the roots of all the upper teeth. There was no ulceration of the gums, though they looked soft and sodden. The breath was very offensive. On the left thigh was one large suggestion about two inches by half an inch. The fundi oculorum were normal. On the 6th the temperature was 101°. There was still slight epistaxis. On the dorsum of the left foot there was a discolouration of the skin evidently due to deep hæmorrhage. A few of the cervical glands on the left side were as large as peas. As regards the fundi oculorum, in the left macular region there were several small irregularly shaped patches. They were greyish white in colour, were not raised, and the largest of them was about one-sixth of the diameter of the disc. There was no sign of hæmorrhage. On the 7th there was a small hæmorrhage in the left fundus below the disc. The spleen was now distinctly palpable. On the 8th the white patches were present

in both macular regions. On the 10th the temperature was 101.4°. The spleen had not enlarged since the last note was made. The glands in the posterior cervical region on the left side were now very numerous and of about the size of peas. There were small hæmorrhages in both fundi. On the 15th there was fresh hæmorrhage from the gums. The temperature since the last note had ranged from

101° to 103°. On the 23rd blood from the median basilic vein was cultivated on bouillon with a negative result. On May 1st the patient's general condition had much improved since the last note. The temperature had been running lower and there had been no more hæmorrhages. The cervical glands could no longer be felt; there were still a few palpable glands in both axillæ and in both inguinal regions. The spleen could not now be palpated. On the 15th, as regards the fundi oculorum, the white patches in the macular regions were becoming very much fainter. On June 11th the patient had very much improved. The temperature had been normal for the last ten days. There was no longer any trace of the white spots in the retina. The patient insisted on going out.

CASE 2.—The patient, a female, aged 21 years, was admitted into the Bradford Royal Infirmary under Dr. R. Honeyburne on August 17th, 1906. On the day before admission the patient began to spit blood and continued to do so till admission. On the same day she noticed that she was covered with spots. She had had no pain in her joints or her abdomen. On admission the temperature was 99° F., the pulse was 96, and the respirations were 20. The patient was a well-nourished girl, moderately anæmic. There was a purpuric eruption all over both legs and thighs and to a less extent over the abdomen, chest, and arms. There were also numerous ecchymoses on the legs, some as large as a four-shilling piece. The gums had continued to bleed profusely since admission, the hæmorrhage coming from the bases of all the teeth. There was no sponginess of the gums.

There were no palpable glands except a few in the posterior cervical regions. With regard to the abdomen there was no tenderness and the liver and splenic dulness were normal. The heart and lungs were normal. The nervous system was normal, as also were the fundi oculorum. On the 19th the eruption was rather more marked; on the inner side of the left thigh were several large sallowings and over both tibiae were distinctly raised nodules. There had been slight abdominal pain and the bowels had moved twice on this date, the motions being almost pure red blood. The gums were still bleeding. Cultures from blood taken from the median basilic vein on bouillon remained sterile. On the 20th there was still some hæmorrhage from the gums. On the 21st the hæmorrhage from the gums had again become profuse and the motions had again showed red blood. The patient was much weaker. There were no hæmorrhages in the fundi oculorum. On the 22nd there were profuse hæmaturia and considerable hæmorrhage by the bowel. The temperature, which had hitherto not been above 99°, rose to 102°. On the 24th the patient had had severe hæmatemesis of bright red blood. The hæmaturia still continued, though slight. From 8.30 A.M. she gradually became comatose and lay without taking any notice of anything and could not be roused. There was no paralysis and the corneal reflexes were present. At 8 P.M. the right corneal reflex was brisk but the left was quite absent. The hæmorrhages had stopped. On the 25th the patient was less comatose. There were now marked nystagmus and definite weakness of the left side of the face. On the 27th she was much better. All hæmorrhage had ceased and she was quite conscious. There was weakness of the left side of the face and of the left sixth cranial nerve. There were also marked blurring and some swelling of both optic discs. The temperature was 99°. On the 31st the patient continued to improve. On the previous night there was again a trace of blood in the urine. On Sept. 9th she had had severe abdominal pains and vomiting during the night but no hæmatemesis. On the 24th she again had severe abdominal pains and the temperature rose to 101°. There had been no hæmorrhages. Between this date and the 27th the patient had had a lot of abdominal pain referred to the umbilical region. There had been no vomiting and the bowels had been regular. The temperature was 101°. On Oct. 16th the temperature had been normal since the last note. The optic discs were now normal. There were marked weakness of the left sixth cranial nerve and slight of the left seventh, otherwise there was no paralysis. On Nov. 10th the patient was sent to a convalescent home.

CASE 3.—The patient, a male, aged 25 years, was admitted into the Bradford Royal Infirmary, under the care of Dr. H. J. Campbell, on Sept. 10th, 1906. Twelve months before admission the patient had had severe hæmatemesis, bringing up about a pint of dark blood. He had had no pain before or after. He was laid up for about five weeks, but since then he had had no trouble and had been able to continue at his work until a few days before admission when he had an attack of severe diarrhoea. There was no history of other hæmorrhages. On admission the temperature at night was 100° F., the pulse was 88, and the respirations were 24. He was a poorly nourished man; his mucous membranes were very pale. Over both cheeks and the whole of the forehead there were very darkly pigmented patches with sharp irregular margins. There was no excess of pigmentation elsewhere. There were small glands of about the size of split peas in both inguinal, both axillary regions, and both sides of the neck. With regard to the abdomen there was no tenderness. The liver dulness in the mammary line extended from the sixth rib to the costal margin. The spleen was felt extending downwards and to the right to within one and a half inches of the umbilicus. Its edge was smooth and hard and was not tender. No notch could be felt and it moved freely on respiration. The patient was exposed to the x rays over the splenic region for ten minutes every second day for two months without the slightest benefit. At the beginning of the treatment the blood was as follows: hæmoglobin, 40 per cent.; and red cells, 3,300,000 per cubic millimetre; after treatment it was: hæmoglobin, 35 per cent.; and red cells, 2,620,000.

Remarks by Dr. FALCONER.—Although the occurrence of hæmorrhages and optic neuritis is not unusual in purpura hæmorrhagica I can find no record of a case of hæmorrhages without previous hæmorrhages. The relative lymphocytosis which was very marked at first, so far as the hyaline corpuscles were

Case 1, although it was there soon replaced by an ordinary post-hemorrhagic polymorphonuclear leucocytosis, is unusual, and suggests the possibility that the white patches were of the same nature as those in lymphatic leukaemia which they very closely simulated in appearance.

I am indebted to Dr. Campbell for permission to publish Case 3, to Dr. Crowley for Case 1, and to Dr. Honeyburne for Case 2.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Discussion on the Diagnosis and Treatment of Laryngeal Cancer.

A MEETING of this society was held on Jan. 28th, Mr. C. A. BALLANCE, the President, being in the chair.

Sir FELIX SEMON opened a discussion on the Diagnosis and Treatment of Laryngeal Cancer. He commenced by referring to the great progress which had been made concerning the diagnosis and treatment of malignant disease of the larynx within the last quarter of a century. It was only by means of early diagnosis that this progress had become possible. He insisted on the diagnostic value of deficiency of movement of a vocal cord from which a suspected growth sprang. He discussed in detail the question of the microscopic examination of intralaryngeally removed fragments of a suspected growth previously to radical operation, and strongly maintained that such microscopic examination should, whenever possible, precede operation. Mere naked-eye examination even by the most experienced observer was very fallacious unless the case was quite advanced. With regard to treatment he entirely rejected intralaryngeal operation and pronounced thyrotomy in early cases of intrinsic laryngeal cancer as the operation *par excellence* for this class of growth. His own experience was founded upon 212 cases of malignant disease of the larynx seen in private practice between October, 1878, and the end of 1906. Of these 136 were intrinsic and 76 were extrinsic or mixed. No less than 177 occurred in men and 35 only in women. He drew special attention to the fact that, whilst the affection was so much more common in men than in women, in the male sex the intrinsic variety, and in the female the extrinsic were disproportionately more frequent, there having been 124 cases of intrinsic and 53 of extrinsic in men against 12 cases of intrinsic and 23 of extrinsic in women. He himself had performed thyrotomy in 34 cases (in one of them the operation had had to be repeated) of real or supposed malignant disease of the larynx. In eight of these the diagnosis had either been shown to be at fault or had remained doubtful. Twice the disease turned out to have been tuberculous and twice of the nature of an infective inflammation, in three cases the diagnosis had remained doubtful, and in one case the growth had turned out to be an innocent papilloma. Three out of these 34 ended by death, giving a percentage of 8.8 fatal results. Of the cases of microscopically verified malignant disease of the larynx, which were 25 altogether, one died and 24 recovered. One of these had been too recently operated upon to be of value for statistical purposes. Out of the remaining 23 cases, genuine local recurrence took place in three cases, giving a percentage of 13.6 recurrence. In one case the patient died from malignant disease of the liver five years after the operation. If this was regarded as a genuine recurrence, the percentage of recurrences would be 17.4. It was, however, considered quite an open question whether this case might not represent a genuine fresh reproduction of malignant new growth. If the question were considered in that light 20 cases would remain in which lasting cure was obtained, or a percentage of exactly 80. These results compared favourably with the results of radical operation for cancer in any part of the body. Out of these 20 cases the cure had lasted over 15 years in one case, in four cases between ten and 15 years, in four between five and ten years, in two over four years, in three over three years, in two over two years, in one just two years, and in one one year and ten months. The reasons were fully stated why in intrinsic cancer of the larynx the one year limit might justly be taken as denoting the critical time during which recurrence might be feared. In 11 of these cases the vocal results were exceedingly good, in five good or fair, and the voice was weak or

reduced to a whisper in four. He still adhered to the technique as stated by him in 1894 in THE LANCET,¹ but briefly described another method, different in several essential particulars, recently recommended by Professor Paul von Bruns of Tübingen. Coming next to hemi-laryngectomy, he expressed the view that this operation would become rarer in proportion as the diagnosis of intrinsic cancer of the larynx was earlier arrived at. He firmly believed that it would ultimately be employed only in cases in which the disease had already invaded the thyroid cartilage or in a few exceptionally favourable cases of extrinsic cancer of the larynx. If performed he thought that it would be better to remove the corresponding cervical lymphatic glands, even if these were apparently not diseased. Subhyoid pharyngotomy was briefly alluded to as being only available in a small percentage of cases. He described his own position with regard to the operation of total extirpation of the larynx as one equi-distant from prejudiced antagonism and from injudicious adulation. He unconditionally admitted the legitimacy of the operation and gladly registered the great diminution of the formerly terrible mortality, nor did he doubt that a few of the patients who had survived the operation for any length of time had been, and were, quite content with their lot. On the other hand, from what he had seen himself, in the majority of these cases life was usually extremely sad and in a very large proportion recurrence took place only too soon. He urgently asked for trustworthy statistics concerning this last-named question and strongly protested against total laryngectomy being undertaken where milder measures were sufficient. In conclusion, he pleaded again for early recognition of the disease in cases of intrinsic cancer of the larynx, by which alone the operator was able to effect a cure by means of simple thyrotomy, a less serious operation which left the patient much less disabled from leading a useful and comfortable existence. It might be possible some day to employ other means than the knife in these cases.

Mr. H. T. BUTLIN submitted an analysis of the results of operations he had performed for malignant disease of the larynx on 35 patients during the last 20 years. Nine of these patients had been operated upon prior to 1890 (seven by thyrotomy, one by infrahyoid laryngotomy, and one by hemi-laryngectomy) and of these three had died from the operation, three from recurrence of the disease, one from some other disease five years later, and two had remained well after three years, giving a total of three successes (33 per cent.) as judged by the three years' limit. The system of after-treatment adopted was of great importance and Mr. Butlin had divided his cases by this date on that account. Since 1890 he had introduced three important modifications into the after-treatment: (1) Hahn's feeding-tube was removed immediately after the operation instead of being left in for two or three days as formerly; (2) the patient was kept in the prone position with the head bent forward so as to avoid discharges running into the trachea; and (3) the patient was made to take liquid food like a dog or a horse with his head hanging over the edge of the bed, so that fluid passing into the trachea readily passed out again. Since 1890 Mr. Butlin had operated on 26 patients (21 by thyrotomy, one by hemi-laryngectomy, and four by laryngectomy). Of these, two had died from the operation, four had died from local recurrence, and one from cancer of the tongue; one had been lost sight of. In two of these patients local recurrence had occurred and 17 had continued well for three years and upwards, giving 65.4 per cent. successes based on the three years' limit. While endorsing Sir Felix Semon's preference for thyrotomy, Mr. Butlin could not help thinking Sir Felix Semon had drawn rather too gloomy a picture of the after-condition of a case of total extirpation (laryngectomy). Speaking of the difficulty in diagnosing malignant disease of the larynx, Mr. Butlin confirmed the desirability of removing a fragment for examination and he did not share the fears that had been expressed by different observers as to the danger of a spread of the growth thereby.

Mr. S. G. SHARTOCK submitted that in the matter of the preliminary histological diagnosis of laryngeal lesions the responsibility lay rather with the operator than the histologist. The positive histological diagnosis of carcinoma presented with few exceptions no difficulty. The result practically depended upon whether the piece of tissue removed by exploratory endolaryngeal operation was really a portion of the lesion or not. The histological diagnosis,

¹ THE LANCET, Dec. 29th, 1894, p. 1532.

however, might be difficult or impossible in the case of a papilloma in which a carcinomatous change had supervened and especially if the latter change had affected part only of the growth. In the case of ulcerating sarcoma, likewise, the differential diagnosis from granuloma might be impossible should the piece removed consist only of a superficial fragment which was the seat of infective inflammation. Intrinsic sarcoma of the larynx, however, was practically an unknown disease. The method of immediate histological diagnosis proposed by Mr. Butlin in the case of the tongue was inapplicable to the larynx; it was impossible to obtain a scraping from the floor of an ulcer *in situ* in order to determine whether it consisted of epithelial cells or otherwise. A piece of the lesion must be removed. As this was done without the use of a general anæsthetic the methods for making an immediate diagnosis, in order that the question of a radical operation might be determined on the spot, were not needed. For the making of an immediate diagnosis (should it be required) the fragment of tissue was too precious to risk the method of teasing; it must be cut into microscopic sections. The tissue could be cut on the freezing microtome in the fresh, unfixed state, though sections so made tended to open out in water and were not easily manipulated. The method of placing the tissue in a small beaker of distilled water and raising the latter to boiling point, after which it could be dipped into gum and cut at once on the freezing microtome, was not satisfactory; the picture was blurred. The most satisfactory method devised was to use a 10 per cent. formal solution in place of plain water in which to boil the tissue. When an immediate diagnosis was not requisite the material could be fixed in salt-formol or alcohol and acetic acid or potassium bichromate and acetic acid, and cut for diagnosis within 48 hours or less. Mr. Shattock preferred the freezing method to paraffin in such cases, for the reason that the orientation of the fragment was of the greatest importance, and on the freezing microtome this could be exactly insured; moreover, in the cut surface of the frozen block the limits of the epithelium, normal and morbid, could be accurately mapped out with the naked eye. In regard to the danger of a local inoculation from an endolaryngeal exploratory operation, this was a real one, should the cutting instrument pass through healthy tissue after traversing the diseased. The danger, however, was of no practical moment, for if a piece of the growth was so removed its nature would be diagnosed and a radical operation would be carried out before time elapsed for any inoculation growth to arise. To attempt the complete removal of a laryngeal carcinoma by a series of endolaryngeal operations only was unsurgical because unscientific and in this country the method was happily quite obsolete. The danger of setting up distant metastasis by an exploratory removal of tissue, he thought, must be extremely remote and could only arise were extensive and violent injury inflicted upon the contiguous structures. He could recall only one instance in which besides a rapid local infection, distal metastasis seemed accentuated by an exploratory operation. The case was one of subperiosteal osteoid sarcoma of the radius which was thought to be an inflammatory enlargement associated with necrosis. The swelling was incised and explored. A rapid local extension of the growth ensued and after death some of the pulmonary metastases found were of recent origin as though due more immediately to the exploratory operation. Such a disturbance of parts was altogether exceptional. No endolaryngeal exploration would be attended with such damage. The chief point raised by Sir Felix Semon, however, was the utility of such preliminary histological examinations. In the case of tumour-like formations of doubtful kind in other positions the practice was a recognised one, and at times it proved of the highest value. But Sir Felix Semon went further; he would apply it in all. To take the case of a neighbouring organ, the tongue, the diagnosis of carcinoma was made, in most cases, from the history and clinical characters. Now and then, even in the hands of the most experienced clinicians, a mistake would arise. And yet there was a certain palliation for the radical operation carried out upon such a mistake; for it was usually true that the lesion taken for a carcinoma was an ichthyosis, with papillary upgrowth, or a leucoplakia, conditions that not infrequently preceded the growth of a carcinoma. That was a matter not touched upon by Sir Felix Semon—the prophylactic surgery of malignant disease. They vaccinated against small-pox; why not operate against carcinoma? But even

if this principle was allowed in the case of the larynx there would still be a small residue of cases in which the proper method of treatment could be determined only by a preliminary histological diagnosis and it was for the sake of these that Sir Felix Semon would have all examined. The proposition compelled admiration but it was a counsel of perfection and like such it would be practised only by the few.

Dr. R. McKENZIE JOHNSTON (Edinburgh) referred to the case of a man, about 50 years of age, who was present at the meeting and who had been operated on 20 months before. Dr. Johnston advocated a preliminary investigation in all cases.

Dr. R. H. SOANES SPICER referred to cases of cancer of the mouth and throat treated by vaccine of bacillus neoformans. Several of these cases were entirely inoperable. Two of these cases, which had been under treatment since March, had made a very notable improvement. One patient was 78 years of age; his weight had improved, the ulcerated surface had become cleaner, and the increase of the growth had been checked.

Dr. HERBERT TILLEY, speaking of the diagnosis, referred to two cases of cancer which were diagnosed as chronic laryngitis, and the cancerous condition had made rapid progress under the escharotic treatment adopted. In cases of suspected malignancy it was most important that the larynx should not be irritated by caustic applications. He had operated on eight cases and he laid stress on thorough scaling of the teeth and rendering the mouth thoroughly aseptic before operation.

Sir FELIX SEMON, in reply, mentioned that it was not always possible without undue violence to remove fragments for examination, but he urged that it should always be done when possible.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Jan. 25th, Mr. H. H. CLUTTON, the President, being in the chair.

Dr. SEYMOUR TAYLOR exhibited a case of Acromegaly. The patient, a woman, aged 32 years, had suffered from increase in size in her hands and feet for about five years. The face was very large, the angle of the lower jaw was obtuse, the lips were pendulous, the ribs and clavicles were enlarged, and the case was otherwise typical in all respects. Her chief discomfort was dyspnoea on lying down at night. Treatment by pituitary extract had yielded negative results.

Dr. F. PARKES WEBER showed a case of Congenital Heart Disease with Cyanosis. The patient was a girl, aged 17 years. When she lay on her back a harsh systolic murmur could be heard all over the heart, but when she stood upright the murmur almost completely disappeared or became much fainter and markedly influenced by the respiratory movements, being best heard during inspiration.

Mr. J. R. LUNN showed a case of Fracture of the Tarsus, occurring in a man, aged 22 years. Some doubtful crepitus could be felt on admission on May 2nd. He stated that he could be jumped a depth of 15 feet, landing on his left foot. The x rays revealed a fracture of the astragalus and a piece of the bone was projecting on the dorsum of the foot. The foot and ankle were put up in a plaster-of-Paris splint which was removed on June 10th, when there was good movement of the ankle. The patient was discharged on July 15th walking well.

Mr. LUNN also showed a case of Achondroplasia. The patient was a man, aged 53 years, 4 feet 1 inch in height. The forehead was prominent; the bridge of the nose was rather deficient, and the eyes were deeply set. The legs were very bowed, there being great curvature of the tibia. The feet were short and square, with all the toes of nearly the same length. There was very little curvature of the bones of the upper limbs. The fingers were more nearly of the same length than normal. The middle and ring fingers diverged at the first interphalangeal joint. The intellect was good.—Dr. R. SOANES SPICER spoke of the cases of achondroplasia that came to the laryngologist with the diagnosis of adenoids on account of the depressed nose and peculiar facial features. Dr. BERTRAM L. ABRAHAM showed an unusual case of Enlargement of the Head in a male child, aged three years. Nothing wrong was noticed with regard to the head until the age of eight months. It then began to swell and continued

to do so for some four months. Dilatation of the vessels at the root of the nose was first noticed at 18 months and progressed since. The child was at present intelligent and well developed. The head was very large, bulging particularly above and to the back; the greatest circumference was 25 inches. On auscultation a systolic bruit was heard all over the head. The right fronto-parietal fissure was closed, but the left, the frontal portion of the sagittal, and both coronal fissures were patent. The left occipito-parietal region was larger than the right. There was venous dilatation over the glabella, involving the left upper eyelid, and descending to within three-quarters of an inch of the tip of the nose. The appearance simulated that of a circoid aneurysm. There was no other abnormal physical sign excepting a systolic bruit over the whole præcordia, loudest in the mitral area, and conducted into the axilla.—Dr. WILLIAM EWART pointed out that the head was not of a hydrocephalic shape, as it retained the normal form.

Mr. H. L. BARNARD showed a case of Successful Plastic Operation for a Syphilitic Perforation of the Hard Palate on the left side of the size of a sixpence. The patient was a man, aged 28 years. The perforation had been present six months. On August 16th, 1906, an -shaped flap was turned in from the right side of the palate and sutured to the freshened edges of the perforation. The flap was about three times the area of the perforation. Healing occurred well. Mr. Barnard remarked that the experience of modern rhinologists controverted the older views about the tendency of such operation wounds not to heal.—Mr. W. G. SPENCER thought that the truth lay between the two extremes and that they could not always expect good results. He described a method that had proved very successful in his experience.—Mr. CHARTERS J. SYMONDS described a modification of the operation. He was sure the results were much better than was previously considered to be the case. However, some forms gave very bad results; such were those in which the alveolar plate was destroyed and those in which the perforation was situate in the soft palate.

Mr. BARNARD also showed a case of Removal of a Stone from each Ureter for Double Pyonephrosis. The patient, a woman, aged 41 years, had had renal colic on both sides, but chiefly on the left, for four years and attacks of cystitis and pyrexia for three years. The radiographic report showed: (1) a stone of the shape and size of an almond in the right ureter opposite the fourth lumbar vertebra; and (2) another, smaller, in the pelvis opposite the fourth sacral vertebra. On Oct. 14th, 1904, the right ureteric calculus was removed through a lumbar incision. The wound in the ureter was closed with catgut. On Dec. 5th, 1904, the left ureteric calculus was removed through an incision in the left fornix of the vagina. The ureter was not sutured. The urinary fistula closed in ten days. The patient was at present well and strong and weighed 9 stones 10½ pounds. The urine was slightly turbid, contained pus, and was acid.—Mr. SPENCER discussed the difficulty of closing the ureter through the vagina.—Mr. BARNARD, in reply, mentioned a case in which the ureter had been pulled down with a hook into the vagina and the opening in it closed. It was important in such an event to use catgut, for it had been found that if silk were used another stone often formed at the site of the ligature. Replying to a question asked by Mr. C. H. FAGGE he said that he had not employed the separator in this case.

Mr. BARNARD also showed a case illustrating a Method of Diminishing the Raw Surface after Removal of Half the Tongue. The patient was a woman, aged 55 years. The right half of the tongue was removed by Whitehead's method. The remaining half of the tongue was doubled back so that the tip was brought in contact with the posterior third. Three catgut sutures were inserted. The advantages of this method were: (1) rapid healing and diminished raw surface; (2) smooth and rounded edge to the tongue; and (3) small scar. The disadvantages were: (1) local recurrence, if it occurred, would be in the middle of the tongue; and (2) the sensation of the tip of the tongue being referred to the throat. The last symptom had disappeared in this case.—The PRESIDENT said that he had employed this method for 23 years and was satisfied with the results thus obtained. Unfortunately, it was rare to get cases early enough for the operation to be suitable for them.—Mr. C. B. KETLEY remarked that an additional advantage of the operation was the diminished tendency to recurrence. The sooner and better a wound healed the less was the chance of recurrence.—Mr. CHARTERS SYMONDS said that he usually employed the method of stitching the edge of the wound to the mucous membrane on the dorsum of the tongue.

Mr. BARNARD also showed a Prostatic Knife for Incising the Floor of the Bladder in total Suprapubic Enucleation of the Prostate. The knife was similar to an adenoid finger curette but terminated in a blunt rounded blade. It fitted on the index finger. This was one method of overcoming the difficulty of cutting on the prostate whilst two fingers of one hand were in the rectum.

Mr. FAGGE showed a case of Carcinoma of the Jejunum; Obstruction; Resection of a Piece of the Jejunum and adherent Transverse Colon; Double Lateral Anastomosis with Murphy's Buttons. The patient, a woman, aged 33 years, was now quite well, 13 months after the operation. The buttons were both passed within six weeks of the operation.—Mr. FAGGE, in reply to Mr. RAYMOND JOHNSON, said that microscopically the growth proved to be a columnar cell carcinoma, with an unusually great amount of fibrous tissue.

Mr. F. W. BROOK showed a case of Multiple Chondromata of the Metatarsal Bones and the First Intermetatarsal Space occurring in a male, aged 50 years. 15 years ago the right "great toe joint" was crushed. This was followed by occasional painless swelling which in the course of a few years became permanent. He was first seen in February, 1904, when the condition differed from that now presented in the following respects. The general swelling was less and not so tense. The calcareous or cartilaginous deposits about the bone were more moveable and the outline of the more superficial ones, which was irregular, was easily recognised. The movements of the joints were scarcely impaired. In the more recent skiagram as compared with the earlier one were seen (1) the increasing amount of the calcareous or cartilaginous deposit in the tissues of, and further widening of, the first interspace, and increasing distortion of the second metatarsal bone; (2) the slow but progressive destruction of the first metatarsal bone; and (3) the appearance of chondromata in the other metatarsals. One of the isolated growths, about half an inch in diameter, was recently removed from the web of the interspace. It was not encapsuled and upon examination by Mr. S. G. Shattock was reported to consist of hyaline cartilage in which small areas of mucous metaplasia occurred.—Mr. BARNARD queried whether the growths might have originated in the tendon sheath.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—A meeting of the Section of Pathology was held on Jan. 4th, Dr. J. F. O'Carroll, the President of the section, being in the chair.—Professor E. J. McWeeney, through Dr. Farnan, exhibited specimens of Uncinaria Duodenalis sent to him by Dr. Christian William Branch, Government medical officer at St. Vincent in the West Indies, where the parasite caused much illness. The exhibit consisted of the washings of the intestine of a child. Two sorts of worms were present—namely, trichocephalus dispar in large tufted masses and uncinaria duodenalis (ankylostoma duodenale). The male and female trichocephalus were very different. The male and female uncinaria were not very unlike each other, the male, however, being the smaller. One measured 7.5 millimetres long by 0.47 millimetre thick. Its remarkable copulatory organ consisted of two spicules, beautifully striated when seen under a high power, surrounded by a sort of umbrella-like arrangement supported by 11 ribs. The female was longer and thicker than the male. One female that was measured was 17 millimetres long. A new species of uncinaria, called uncinaria americana, parasitic in man, was described in 1902 by Stiles, and is now made into a new genus called necator. It occurs in the same locality as uncinaria duodenalis and does a great amount of mischief, especially to children, causing retardation of development, anaemia, and cachexia. In Europe the parasite chiefly attacked miners and attention was first called to it in connexion with the boring of the St. Gotthard tunnel in Switzerland in 1880, when it caused a serious outbreak of "pernicious" anaemia amongst the workmen.—The President described a case of Suffocative Hydrothorax in which the Pleurae were tapped several hundred times. The patient was a robust and intelligent man, 65 years of age, who entered a hospital in May, 1900, suffering from great distress in breathing and epigastric pain. There were considerable swelling and tenderness in the epigastrium. The urine, small in quantity and dark in colour, contained some sugar. There was a faint systolic apex murmur, together with some dulness in both pleurae. A month afterwards the right pleural cavity was tapped and 40 ounces of fluid were withdrawn. Two days later the left pleural cavity

was tapped, 76 ounces being withdrawn. Occasionally, as might have been expected, there was a trace of albumin in the urine. A slight purplish tinge was visible through the patient's natural ruddiness and the veins in his neck were slightly more prominent than they would ordinarily have been. He had also at first some oedema of the legs. During the first four or five months the two pleurae were tapped almost alternately. Thereafter the right one was tapped about twice for every time the left was tapped and this proportion was maintained till March, 1902, when the left pleural cavity ceased to secrete as the result of an adhesive pleuritis. He had then to be tapped twice as often on the right side, and this went on, practically every second day, to the amount of 50, and 60, and 70 ounces till the beginning of May, 1903, almost three years after his admission. Then the right pleura began to show signs of not yielding as much fluid as formerly and of being annihilated by adhesive pleuritis of rapid course. He died when this was complete, practically as if he had been garrotted in such a way as to stop the venous flow into the heart without obstructing the trachea, the process lasting about two days. He had spent three years all but five days in hospital, had hardly lain down in bed for more than two or three hours nightly all that time, but had retained his original weight, appearance, and good spirits up to the closure of the right pleural cavity three days before death. At the necropsy, when the heart was examined and the vena cava superior was slit up, a prominence in the posterior wall of the vena cava was noticed. This was an aggregation of tuberculous glands of no great bulk; but the real mischief was caused by an actual fusion of the gland mass with the wall of the vena azygos, the girth of which at this point was half that immediately to the right of it. The total amount of fluid withdrawn during the three years was computed to weigh about three-quarters of a ton.—Dr. F. C. Martley instanced a case bearing some similarity to that described by the President.—Dr. Thomas G. Moorhead exhibited a specimen obtained after the Talma-Morison Operation. The patient, who was a woman aged 22 years, was admitted to a hospital in April, 1906, suffering from ascites which had developed in a couple of days. After tapping an operation was decided upon. The liver was found to be enlarged, firm, and hard. The surface was scraped and the great omentum was stitched to the abdominal wall. After the operation the patient was tapped at intervals of 10 days—200 ounces of ordinary ascitic fluid being withdrawn. About two months ago she began to lose weight. It was decided to see what could be done to establish a permanent drain to the peritoneum but no improvement took place and the patient afterwards died. The interest of the specimen was in showing the results of a Talma-Morison operation six months after its performance. At the necropsy adhesions across the anterior abdominal wall were found and along these could be seen the development of new superficial veins, chiefly between the two peritoneal surfaces. The operation was therefore partially successful in causing the hoped-for establishment of new collateral channels. That it was not more successful was probably due to the fact that the patient, in addition to cirrhosis, had a nutmeg liver. In most cases of cirrhosis some alcoholic history could be obtained. This patient, however, had been a teetotaler all her life, but on inquiry it was found that part of her occupation was the putting of photographic negatives into methylated spirit, which might have something to do with the case.—Dr. William Wheeler instanced a case in which, after finding an enlarged liver roughened on the surface, he performed a Talma-Morison operation. That was two years ago. The patient was tapped once after the operation but never since. He had been extremely well and had gained three or four stones in weight. The other day he came to show himself; no tapping was required, but on examination the urine showed a good deal of albumin, giving signs of a cirrhosis of the kidneys. In 90 per cent. of the cases in which there were no complications ascites was got rid of by the Talma-Morison operation.—Dr. Henry Earl said that in many cases of cirrhosis, such as the question in many cases of cirrhosis occurring in children. A great number of the patients met with in hospital practice drank all they could get, and if cirrhosis of the liver had any intimate connexion with alcoholic indulgence it should be one of the commonest affections, which it was not by any means.—A meeting of the Section of Surgery was held on Jan. 11th, Mr. H. R. Swanzy, the President, being in the chair.—Mr. L. G.

Gunn made a communication on the Treatment of Enlarged Prostate. He said that, in his opinion, too much attention was paid to the operative treatment of this affection. As many cases could be greatly benefited, though not actually restored to health, by non-operative treatment, it was well to consider this before advising a patient to have the gland removed. Mr. Gunn then gave a brief account of work which he had seen at Paris, London, and Berlin. In the first city prostatectomy was hardly ever performed, in London it was always advised, while in Berlin palliative measures were often used. He then gave a short account of 41 cases of enlarged prostate which he had treated. Of these cases 11 had required operation; nine had made good recoveries, and two had died. 19 cases had been treated by palliative means with more or less relief. None of these had to use a catheter, as Mr. Gunn believed that the risks of catheter life must be always greater than the risk of an operation.—Dr. J. Walton Browne said that much good could be done by washing out the bladder.—Mr. O. A. K. Ball expressed the view that a large number of cases had been operated on in the past which, no doubt, would have lived, and, perhaps, in a more comfortable state, had palliative measures been tried instead of operation. He thought that palliative measures ought to be employed unless there was absolute obstruction to the flow of urine.—Mr. Alexander Blaney said that many cases which had ended fatally after operation would probably have been successful had radical measures been carried out earlier.—Mr. S. Horace Law described an Early Case of Leontiasis Ossea occurring in a boy. When Mr. Law first saw him four years ago he was 12 years old, small for his age, but upright and sturdy. He seemed to be in good general health and his only complaint was of nasal obstruction. On examination a hard bilateral growth was seen in the infra-orbital region, extending up in such a way as to cause the eyes to be pushed outwards and also to bring about exophthalmos. The lateral walls of the nose were pushed towards the middle line so as to occlude the nostrils, though a probe could be passed up to the sphenoid bone and air could be blown through the nose. The naso-pharynx was not involved. The pharynx and palate were normal. The antra of Highmore were dark to transillumination and when an ordinary antrum drill was passed in through the canine fossa on the right side it failed to reach a cavity. The bone was soft and spongy. In November, 1906, the peculiar enlargement due to the disease was well marked. The patient had dacryocystitis on both sides. X ray photographs showed dense shadows corresponding to the obvious growths and a shadow of growth lying between the orbits. The cranial vault of this youth was of about the same thickness as in an adult.—The President said that he regarded the dacryocystitis not as a coincidence but rather as the direct result of the bony growth. He thought that the best mode of treatment would be extirpation of the lacrimal sac on each side, as, in existing circumstances, ulceration of the cornea of a very intractable type would be likely to occur.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on Jan. 18th, Mr. G. Pernet being in the chair.—A paper was read by Dr. C. O. Hawthorne entitled "Protection of Rheumatic Children," in which he asked whether anything could be done to prevent or to limit the occurrence of cardiac disease in children who were known to be liable to such disease as a result of a rheumatic inheritance or proclivity, irreparable damage being frequently inflicted on the cardiac tissues by the rheumatic poison almost or altogether apart from incidents popularly recognised as rheumatic. The disproportionate frequency of heart disease in children might be due to the absence of arthritis in them and therefore there was less tendency to keep the patient at rest. It was necessary to educate the public as to the value of rest, and when this was done there might be a diminution in the incidence of heart disease in early life with its diminished usefulness of the individual.—Mr. J. P. Lookhart Mummery read a paper on Volvulus of the Small Intestine round a caecum, which was gangrenous and on the point of giving way in several places. This was resected and the cut ends were united with Murphy's button. The case resembled appendicitis, the classical symptoms of acute obstruction of

the small intestine being not at all prominent. Vomiting was a marked feature early but had ceased when the child went to the hospital and was never fatal. There was no distension of the abdomen.—Dr. Hawthorne showed: (1) A case of Dilatation of the Stomach of doubtful causation in a boy, aged 12 years; and (2) a patient showing the result of an operation for Extreme Depression of the Frontal Bone.—Dr. Edmund Cantley showed a girl, aged nine years, with Diabetes Insipidus. For two years she had had nocturnal enuresis and for six months enuresis diurna also, with thirst and excessive appetite. The urine varied from 46 to 262 ounces per day, was pale, acid, of specific gravity 1005 and contained from 0.5 to 0.9 per cent. of urea. Adrenalin and atropine had effected no improvement but valerianate of iron and quinine with strychnine were more successful, the polyuria and thirst diminishing and the patient gaining weight. There was no exciting cause discovered and there was no sign of chronic interstitial nephritis.—Dr. F. J. Poynton showed: 1. A case of Premature Development in a child aged two and a half years. The remarkable growth began when the child was a year old, pubic hairs and sexual development being then noted. The weight was now 3 stones 1 pound. The circumference of the head was 20 inches; of the thorax, 22½ inches; and of the abdomen, 23 inches. The length of the whole arm was 12 inches and of the leg 17 inches. The voice was deep and memory was good. The aspect was rather suggestive of acromegaly. There was no suprarenal tumour to be felt. The parents were small and healthy. 2. A case of Friedreich's Disease (?) in a girl, aged nine years. Five years ago the child had measles with severe cerebral symptoms and had not been well since. She had now well-marked ataxy of the legs and incoördination with tremor of the hands. There was doubtful nystagmus. The knee-jerks were abolished. The right plantar reflex was extensor, but the left was flexor in type. There was some lordosis of the upper dorsal spine. Double pes cavus was present. The speech was slow. There were no optic changes.—Dr. G. Carpenter showed a case of Oedema in an infant who was 14 months old and weighed 7 pounds; the oedema of the face and limbs followed an attack of diarrhoea. The child was anæmic and the temperature was subnormal. The urine contained no albumin.—Mr. Lockhart Mummery showed a case of Webbed Penis. The penis was inclosed within the scrotal skin right down to the tip; there were no other abnormality and no history of similar defects in the family.—Dr. G. A. Sutherland showed: 1. A case of Congenital Cerebellar Ataxy (?). The patient, a boy, aged three years, had suffered from general ataxy for 18 months. He was healthy at birth but had convulsions at the age of six months. At the age of two years he was unable to sit or stand without support and the limbs were tremulous and ataxic. The speech and intelligence were very backward. The knee-jerks were very active. There was double internal squint and the optic discs were pale but not definitely atrophic. The condition had remained the same for the past nine months, except that now the child could sit unsupported. Dr. Sutherland thought it probable that the case was one of birth palsy following meningeal hæmorrhage and probably involving the cerebellum. 2. A case of Congenital Deformities of the so-called Mongolian type of Amentia. The patient, a girl, aged eight years, showed the shortening and curving of the little fingers and the oblique palpebral fissures so characteristic of Mongolian imbecility; but the patient was perfectly intelligent and had no cranial deformities. She was under treatment for fibroid phthisis.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held in London on Jan. 11th, when Dr. D. S. Davies, the medical officer of health of Bristol and President of the society, delivered his presidential address, dealing mainly with some points in the life history of two of the commoner communicable diseases. Commencing with the subject of diphtheria, he said that this disease was more or less endemically prevalent in all large towns, but the periods of fatal prevalence recurred not after the manner of measles at fairly constant and somewhat short intervals, but at long and uncertain intervals after a prolonged period of comparative, and often remarkable, quiescence. The progress of an epidemic appeared to follow a course, determined partly by the virulence of the type introduced and partly by the resistance of the individuals attacked. During the first months the introduced infection was somewhat limited in distribution and at this stage hospitals

might prove of far greater service in prevention than later. The essential towards prevention was an efficient organisation for the bacteriological examination of throats and noses in all "contacts," whether members of an infected household or class-mates in an infected school. There was no antagonism between scarlet fever, measles, and diphtheria; if anything, one predisposed to the other. The largest number of mixed infections were of diphtheria upon scarlet fever. School examination of "contacts" in infected classes was a more rational procedure in urban communities than mere school exclusion without such examination, and if there was sufficient staff available to carry this out promptly and thoroughly there was little risk to the children; but it must be remembered that there might be home "contacts" who had to be sought for and dealt with also. The difficulty met with in London owing to the inaction of certain authorities had not been felt at Bristol, as the whole of the work of school visitation and examination had had, in default of any education medical officer, to be carried out by the health department. Speaking next of small-pox, Dr. Davies said that this disease, in spite of its high infectivity, was comparatively easy to control. In common with the majority of the common communicable fevers, the spread of this disease was for the most part immediately personal. A patient either definitely had, or had not, small-pox at any particular time; he never merely carried it on his living tissues in an inert, but to others a potentially infective form. Hence hospital isolation with protection of "contacts" was generally successful in this disease. The control of small-pox from introduced centres depended on a careful personal search for "contacts," and the use of experience and judgment in looking for them in the right place. In the evening the annual dinner was held at the Holborn Restaurant, the chair being taken by Dr. Davies, and among others present were Mr. Colston Wintle, Colonel J. Lane Notter, Sir Shirley F. Murphy, Dr. B. Arthur Whitelegge, and Dr. Dawson Williams. In proposing the toast of the "Society of Medical Officers of Health," Mr. Wintle said that it had now ten branches and a membership of upwards of 1000, practically every medical officer of health being a member.

HARVEIAN SOCIETY OF LONDON.—A clinical meeting of this society was held on Jan. 24th, Dr. Sidney P. Phillips, the President, being in the chair.—The President showed a case of Congenital Heart Disease. The patient was a boy, aged nine years. There was a loud systolic murmur over the aortic cartilage; cyanosis was not present. The condition was probably one of congenital narrowing of the aorta.—Mr. W. H. Clayton Greene showed a case of Bilateral Cystic Disease of the Kidneys in a man who had come under treatment for hæmaturia; both kidneys were greatly enlarged. The question of treatment was discussed and in view of the hopelessness of these cases the possibility of kidney grafting was raised. It was suggested that a kidney might be grafted into the scrotum, the spermatic vessels and vas deferens being used to take the place of the renal vessels and the ureter.—The case was discussed by Dr. J. F. H. Broadbent, Mr. T. Crisp English, Dr. B. H. Spilsbury, and the President.—Dr. L. Colebrook showed (for Mr. S. Maynard Smith) a case of Dislocation of the Shoulder, with a fracture through the lower part of the glenoid cavity. The patient was an elderly woman and the injury had occurred four months previously; a skiagram was shown.—Dr. F. Langmead showed (for Dr. H. A. Caley) a case of Aneurysm of the Innominate Artery and raised the question of surgical treatment.—The President discussed the case and considered it unsuitable for operation. He pointed out the difficulties in exact diagnosis and also the general degeneration of the patient's arteries which were in unsatisfactory condition for ligation.—Mr. Crisp English showed a man, aged 62 years, with a Large Tumour of the Left Breast. This had existed for 12 years, had greatly increased during the last 12 months, and was mainly cystic. In its upper part was a small indurated and nodular area.—Mr. F. Jaffrey thought that the hard portion might prove to be sarcomatous.—Dr. Spilsbury considered that the tumour was probably an innocent cystic growth.—Mr. Jaffrey showed a woman, aged 40 years, with a Fracture of the Lower End of the Radius and Wasting of the Muscles of the Hand. In spite of continued massage the condition had improved but slowly, and it was questioned whether any nerves had been injured.—The President showed a man suffering from General Paralysis of the Insane with atypical

symptoms.—Dr. Broadbent showed a case of Paralysis of the Third Cranial Nerve of rapid onset in a woman, aged 30 years; improvement was occurring under treatment with potassium iodide. It was pointed out that certain of these cases of nerve paralysis ultimately developed locomotor ataxia. —The President and Mr. Crisp English discussed the case.

THERAPEUTICAL SOCIETY.—A meeting of this society was held on Jan. 22nd, Dr. T. E. Burton Brown, the President, being in the chair.—Mr. F. H. Bonnefin read a paper entitled "Short Notes on a Method for Rendering Creasote and Cannabis Indica Soluble and on some Little Known Medicinal Remedies." He showed clear solutions both of creasote and of cannabis indica which he prepared by the following formulae:—1. For making creasote soluble: Decoctum quillaiæ concentratum (1 in 7), 2 parts; solutio sodii salicylatis puri (1 in 2), 1 part; and creosotum optimum, 1 part. Shake and warm very gently. 2. For making cannabis indica soluble: Extractum cannabis indicæ (physiologically tested), 1 part; spiritus vini rectificatus, 4 parts; decoctum quillaiæ concentratum (1 in 7), 7 parts; and aqua destillata, 8 parts. Mix the extract with the alcohol, warm, add warm decoction of quillaiæ, shake; finally, add warm distilled water, shake, and strain after three days. He showed how each solution remained clear on adding either water or acid, so that no precipitation would take place in the stomach.—In the discussion which followed Mr. W. Soper, Professor A. R. Cushny, and Professor R. B. Wild took part, when evidence was brought forward to show that these preparations contained no active principles, and that after due consideration they had been deliberately omitted from the U.S. Pharmacopœia as inert.—Professor Wild then read a paper on the Proper Scope of the Teaching of Materia Medica, Pharmacology, and Therapeutics in the Medical Curriculum, in which he endeavoured to arouse the interest of medical men in the better teaching of therapeutics. He laid stress on the fact that while great changes had taken place in the practice of therapeutics during the past twenty-five years, there had not been corresponding changes in the teaching of the medical student. At the present time the chief obstacle to any reform in the teaching of materia medica and therapeutics lay, he thought, in the great diversity in the requirements of the various examining bodies, and some general agreement was urgently required as to what should be insisted upon as an essential minimum for qualification, and what had become obsolete and might well be removed from the overcrowded curriculum.—Professor Cushny, Dr. J. Gordon Sharp, and the Secretary joined in a discussion on the paper and agreed with Professor Wild's conclusions.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on Jan. 23rd, Dr. Leslie Roberts, the President, being in the chair.—Mr. G. W. Dawson showed: 1. A boy, aged 11 years, with Tinea Tonsurans to illustrate the rapid and complete clearance of all diseased hairs after only four exposures to the x rays. 2. A woman, aged 45 years, with Acute Lichen Planus of five months' duration. The eruption was of an annular type and widespread and the patient's general health had suffered much at the onset of the illness. She was being treated with salicin.—Dr. A. Eddowes showed a young woman with Acrodermatitis Hiemalis of nine years' standing. The hands were much congested and presented numerous scars the result of deep-seated nodules which had come to the surface and ruptured. The case was commented upon by many of the members who pointed out the likeness of the condition to folliculitis (Bartholomy), to chilblain-impus (Hutchinson), and also to scrofuloderma.—Dr. E. G. Graham Little presented a case for diagnosis in the person of a woman, aged 33 years, in whom a Scaly, Papular Eruption had appeared three weeks ago, accompanied by a dryness and irritation of the whole integument. The condition seemed to resemble lichen planus, but it was generally conceded to be the result of some severe toxic infection.—Dr. J. H. Stowers showed a boy, aged nine years, with a Small Nodule upon the Right Cheek. The child was said to have been bitten by a mosquito on this spot seven months previously. None of the members were satisfied that the lesion was tuberculous in nature.

BURNLEY AND DISTRICT MEDICO-ETHICAL ASSOCIATION.—A meeting of this society took place on Jan. 24th, Dr. J. S. Wilson, the President, being in the chair.—Dr. A. Macgregor Sinclair showed four tumours of Ectopic Gestation which he had recently removed from patients. He gave

histories of each of the cases and laid especial stress upon each of the women having been sterile for several years and having had an offensive leucorrhœal discharge during the period of sterility, and reasoned from these facts that "ectopic gestation" was probably due to diseases either of the uterus or of the tubes. Each case was marked by the usual symptoms of abdominal pain and bloodlessness before operation and a well-marked pulsation in the fornix of the side upon which the tumour was situated. The fourth case differed from the first three, inasmuch as it was complicated by an adherent inflamed appendix and the earlier abdominal symptoms were obscure. On operating, the right tube, which contained a three or four months' foetus, was twisted round behind the uterus and attached to the appendix, and though it was ruptured only a small amount of hæmorrhage had taken place because the tear in the tumour was filled by the protruding head of the foetus. The cases were all treated in the ordinary aseptic manner and made uneventful recoveries.—Dr. H. J. Slane, Dr. R. O. Holt, and the President took part in the discussion.—Mr. J. H. Carter, F.R.C.V.S., who was present, related a case of Ectopic Gestation in a Newfoundland bitch.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on Jan. 9th, Dr. T. Colcott Fox being in the chair.—Dr. S. E. Dore showed for Dr. J. J. Pringle a case of a Bullous Disease, with the clinical features of dermatitis herpetiformis, in a man who had been under treatment for five years with arsenic. The eruption was controlled by doses of six minims of liquor arsenicalis, but the patient had latterly shown very serious symptoms of arsenical poisoning. He had pigmentation over almost the whole body, keratosis of the palms and soles, and increased knee-jerks.—Dr. J. H. M. MacLeod showed a case of Lichen Planus which had commenced with curious patches of hypertrophy of the epidermis of the knees before the appearance of more typical patches of lichen planus on the wrists had cleared up the diagnosis. The hypertrophied patches had disappeared under treatment by the x rays.—Dr. E. G. Graham Little showed an unusual case of Lupus Erythematosus, involving the scalp alone, in a medical student. The largest patch was of a band shape and had persisted for three years. Dr. Little also showed a case of what was clinically almost certainly Lupus Vulgaris of the Nose and Upper Lip in a young girl, but repeated estimations of the opsonic index showed a normal figure for tubercle and only 0.6 for streptococcus. The clinical diagnosis was supported by the opinion of the meeting.

Reviews and Notices of Books.

A Text-Book of Psychiatry for Physicians and Students. By LEONARDO BIANCHI, M.D., Professor of Psychiatry and Neuropathology in the Royal University of Naples, Minister of Public Instruction, Medical Director of the Provincial Asylum, Naples. Authorised Translation from the Italian by J. H. MACDONALD, M.B., Ch.B., Glasg., Senior Assistant Physician, Govan District Asylum. London: Baillière, Tindall, and Cox. 1906. Pp. xvi.-992. Price 21s. net.

THIS important treatise opens with an introduction of 23 pages, which constitutes a brief review of the evolution of the mental faculties. Then follows an anatomical description of the cerebral mantle with an account of the motor and sensory paths and centres, of associative paths, and of the minute anatomy of the cortex. The latest observations are recorded. The neuron theory, that of continuity of the neuro-fibrils, and the functions of the neuroglia are discussed in the light of recent research. The physiology of the cerebral mantle is also dealt with at length; thus, the physiology of vision, movement and speech, Flechsig's doctrine of associative areas, and the physiology of the frontal lobes (so important as organs of the highest psychic functions). Some 150 pages (constituting Part I. of the book) are given to the anatomy and physiology of the cortex cerebri.

Part II. treats of the physio-pathology of the various mental processes; thus, the physio-pathology of perception, attention, memory, will, and so on. No less than 100 pages

are devoted to the analysis of these processes in health and disease. Indeed, the domains of anatomy, physiology, and physiological psychology are perhaps somewhat too extensively invaded. The anatomical substrata of the various mental processes are discussed, it being shown that narrow conceptions of localisation cannot be entertained, the area of formation and conservation of these processes being widely diffused. In the synthesis of psychical processes the frontal lobes are mainly concerned. With respect to consciousness also the frontal lobes constitute the chief centre, though its anatomical substratum is co-extensive with the entire cerebral mantle.

Mental disorders proper are considered in Part III. (477 pages), which opens with a chapter on the methods (psychological, anthropological, and neurological) and upon the scope of clinical inquiry. The classification adopted is, in view of the "impossibility of holding to a single criterion," based upon "nosological, ætiological, and anatomic-pathological criteria." Mental affections are divided into three groups, each of which has some characteristic feature; thus in those of the first group there is always a primary defect due to want of cerebral development (congenital moral insanity, epilepsy, fixed ideas, and so on); the second group comprises affections of toxic origin supervening in normally developed persons (such as mania, confusional states, and alcoholic and morphine insanity); and the third group includes disorders with demonstrable anatomic-pathological alterations in the brain (paralytic, senile dementia, dementia of focal lesions, and the like). The remainder of the book is occupied with the discussion of the individual members of these groups. Idiocy is described under "Phrenasthenia"; objection may be taken to such a limited application of the latter term. Sub-groups of idiocy and imbecility are not described for the reason that they are artificial. Under "Paraphrenia" come the eccentrics, "cranks," fanatics, and such like borderland cases. Under "Delinquency" are considered the anti-social or criminal classes. The author distinguishes between the criminal born and the criminal from acquired habit but does not admit an anthropological type of delinquent. Modern views upon the toxic origin of epilepsy are discussed; the anatomical changes found in the brains of epileptics are regarded as effects and not causes. 37 pages are devoted to "hysterical insanity" but under this heading ordinary hysteria is also described. The author is no advocate of hypnotism though he recognises the occasional benefit derived from various forms of suggestion. In regard to paranoia, *quot homines, tot sententiæ*; we are not surprised to find that Professor Bianchi has views of his own. The manifestations of this disorder would appear to vary much in accordance with the nationality of the patient and to be peculiarly susceptible to local colouring. The remaining disorders of the first group are obsessions, neurasthenia, and the sexual psychopathies. In introducing the disorders of the second group reasons are given for the belief that they are due to the entrance of endogenous or exogenous toxins into the blood stream. The chief members of the group are mania, melancholia, "sensory" insanity, acute delirium, and alcoholic insanity. Pure mania and melancholia are recognised apart from "manic-depressive" insanity. "Sensory" or hallucinatory insanity (an unusual designation) covers the various conditions included by others under dementia præcox. The chief disease of the third group is naturally paralytic dementia, to which 45 pages are devoted. Modern views as to its etiology and pathology are fully discussed and it is shown that great uncertainty still exists on these points. Short chapters on other forms of dementia due to organic lesions bring this comprehensive treatise to a conclusion. The book is freely illustrated.

Professor Bianchi's high reputation in the field of psychological medicine led many to welcome the announcement

that an English translation of his work had been undertaken. The book gives evidence throughout of its distinguished author's great experience, industry, and scientific impartiality, and he exhibits a truly cosmopolitan acquaintance with the literature of his subject. He has produced a standard work. With but rare exceptions we find the English of the translation clear and readable.

Growth, A Novel. By GRAHAM TRAVERS (MARGARET TODD, M.D. BRUX.). London: Constable and Co. 1906. Pp. 418. Price 6s.

"GROWTH" more than fulfils the early promise of the author who gained so wide a circle of admirers by her first novel, "Mona Maclean, Medical Student." This later and more mature work will appeal to the large public of thoughtful readers who appreciate a sympathetic study of the momentous years of student life, those most important and fertile years of mental and moral growth in the history of the individual.

The hero, Dugald Dalgleish, only son of a widow, leaves his country home as soon as he can gather together funds enough (12s. a week) to enable him to go to the University of Edinburgh to study for the ministry. An enthusiastic idealist eager for knowledge, the young Calvinist is thrown into the society of kindred intellects, and takes a prominent part in the debating societies which form such important influences in the lives of a nation proverbially prone to love argument on theological and metaphysical matters. The overwhelming inrush of new ideas born of modern science and philosophy unites to shake the very foundations of the young man's being; his studies are neglected and for a time his character is altered for the worse. He is saved from sinking to any depth by three strong influences—the friendship of the heroine Judith, love for a beautiful actress, and hero-worship of his senior fellow-student Thatcher. Judith understands the lad's state of mind and administers doses of praise or blame and renders unselfish assistance whenever necessary. Her gospel is the Human Brotherhood and her life is steadfastly devoted to helping lame dogs over stiles. Regardless of conventions, with strict ideals of duty, yet not lacking in humour and in readiness to admit her errors and prejudices, combining the intellectual honesty of man with the sympathy and loveliness of woman, Judith presents one of the most attractive types of modern womanhood in fiction and the reader is the richer for having made her acquaintance. Ianthe Brooke, the actress, is a less real figure, but the bewilderling effect of her grace, charm, and beauty on the raw lad who had been brought up to regard beautiful things and pleasures as works of the devil is carefully and truthfully portrayed. Thatcher, the ascetic hero, forms an interesting study of the conversion of a Puritan to Roman Catholicism.

We may here mention that the author should not have described a typical group of Scottish students in Edinburgh as belonging to a Nonconformist chapel with a pastor. It would have been more in keeping with local colour had she associated them with a minister and a seceding kirk, and what she describes is, in fact, such a community.

The numerous other characters in the novel all illustrate a definite outlook on life, showing their individual solution of the problem of the meaning of life and duty and their relation towards God. It is greatly to the credit of the author that the underlying religious *motif* of the book is not too much in evidence; the characters live, they are not mere shadows who repeat formulae in order to promote their creator's belief in a particular creed. In this respect "Growth" stands far above the average novel with a "religious purpose." The attitude of doubt, the criticism of each and every creed and church, natural to a group of honest young students, is truthfully depicted; and the ultimate adhesion to one or another church, according to the

individual's temperament and ability, as described by the author, is true to life. The good in every church is generously illustrated; the evil and the limitations are but lightly mentioned. Thatcher and Carew represent the advanced intellectual type of Roman Catholic; Frances and Monsignor the emotional type, to whom dogma and tradition are as necessary as the air they breathe. Mr. Atherley, the pastor, is the foil to Father Bernard; both acquit themselves equally nobly; both are ornaments to their respective churches.

Less happy, we consider, is the portrayal of the final effect of the new scientific and philosophical thought on Dalgleish and his sister Grizel. The following suggestive paragraph should have served as a text for the final chapters of the book: "To his great delight, he had started Logic and Metaphysics. Day after day he drank in the lectures as a thirsty soul drinks in the rain. To be given the forms of thought, combined with such freedom to think, was a privilege he had ceased to expect from his pastors and masters, and it was beneficial as much from a moral as from an intellectual point of view. Little as he suspected the fact, freedom of thought had come of late to mean for him something perilously like lawlessness. The new studies had pricked that bubble for ever." Many a young student, when deprived of his belief in dogmas, has imagined that religion and morality necessarily fall at the same time; but a deeper study proves to him that religion and morality not only remain unaffected but are natural forces all the stronger and more convincing for their lack of artificial props. Dalgleish and Grizel are shown in their first stage of despair and sadness, bravely accepting Truth but unconsoled for the loss of their ancient and dear beliefs. But if they lost some loved beliefs they also lost many cramping and cruel beliefs. By means of their new knowledge they gained a wider, grander faith, with endless vistas of glorious promise, and they acquired a nobler conception of God, one more in harmony with the great movements of the universe revealed by scientific research. Of a surety, after a few unsettled years of mental bewilderment, the happiness and comfort of their newer knowledge would have more than recompensed them for their incapacity to regard life from the same standpoint as their saintly mother. This more advanced stage of reconnoitment and peace is hinted at rather than described and for this reason the book to many readers will appear incomplete, like a noble song brought to a sudden end before the final note of triumph has been sung.

We can confidently recommend this novel as a work of art, describing a side of life which is but rarely met with in fiction. Novels professing to deal with student life usually depict games, slang, and convivial gatherings; the inner turmoil of the awakening active young spirit, the idealism, and the earnest seeking after truth are equally true and more important aspects of student life, and it is these that "Growth" so capably and sympathetically describes.

Medical Electricity. By H. LEWIS JONES, M.D. Cantab., Medical Officer in charge of the Electrical Department, St. Bartholomew's Hospital. Fifth edition. London: H. K. Lewis. 1906. Pp. 519. Price 12s. 6d. net.

LITTLE more than two years have elapsed since we reviewed the fourth edition of this important work. In the interval the author has almost entirely rewritten the book and has also rearranged the contents, besides deleting some parts which were unnecessary. All the changes which have been thus brought about serve to increase the value of the book.

The historical chapter with which the previous editions opened has been omitted, and Chapter I. now forms a useful introduction to elementary physics, where those who wish may refresh their memories with regard to the fundamental principles of the whole subject. The next six chapters deal with apparatus in a very thorough manner, from the simplest

form of medical battery to the latest development in high potential electricity. Chapter VIII. is devoted to Roentgen Rays and forms a very excellent and trustworthy *résumé* of the present position of this branch of work. Next follows a chapter on physiological considerations, in which the general effects of the various forms of electricity on the tissues are fully gone into. Then come others on general diseases, the nervous system, circulatory disturbances, special senses, and the skin.

We notice that the special chapters on electricity in surgery and the electric bath are now done away with and the matter is distributed around the chapters on apparatus or therapeutics as may be most desirable. The chapter on diagnosis has also disappeared as a separate entity and is incorporated in the chapters dealing with the nervous system, to which it more properly belongs.

The whole book has been brought entirely up to date and in our opinion is likely to maintain the position which it has long held as the standard work on medical electricity in this country.

LIBRARY TABLE.

Atlas of Applied (Topographical) Anatomy. By Dr. KARL VON BARDELEBEN and Professor Dr. H. HAECKEL. Authorised English adaptation from the third German edition, containing 204 woodcuts in several colours and descriptive text. By J. HOWELL EVANS, M.A., M.B., M.Ch. Oxon., F.R.C.S. Eng. London and New York: Rebman Company. 1906. Large crown 4to. Price 32s. net.—In preparing this adaptation of Bardeleben's well-known atlas Mr. Howell Evans has been guided in his selection of plates by their relative clinical importance. Those regions of the body which have of recent years become of increasing interest have received particular attention. We find especial prominence given to the anatomy of the tympanum and its accessory cavities, to the air sinuses of the face and base of the skull, to the Gasserian ganglion, and to the surgical anatomy of the gall-bladder, bile ducts, pancreas, and organs of the male pelvis. The anatomy of the limbs is well illustrated but the plates possess no distinctive features. We notice that the "sigmoid flexure" is still described and that the cutaneous segmental nerve areas are not figured in accordance with the views of English observers. The atlas will, no doubt, find its sphere of usefulness but as it is not provided with an index speedy reference to any desired point is very difficult.

The Development of the Human Body: a Manual of Embryology. By J. PLAYFAIR McMURRITCH, A.M., Ph.D., Professor of Anatomy in the University of Michigan. Second edition, revised and enlarged. With 272 illustrations. London: Rebman, Limited. 1906. Price 14s. net.—Without pretence at originality Professor McMurrich presents the subject of human embryology in a very readable and convenient form. His descriptions are lucid and at the same time concise. Moreover, by avoiding reference to highly controversial matters the attention of the reader is not distracted from the essential of the subject. The result is a text-book well adapted to the needs of the ordinary student. The book is divided into two parts, of which the first is concerned with general development, whilst the second deals with the formation of the various systems and organs, concluding with a chapter on post-natal development. The volume is well illustrated, mainly by figures from various well-known authorities on the subject. We are not surprised to find that a second edition has so soon been called for.

Muscles and Nerves: an Atlas of the Superficial Muscles and Principal Motor Nerves of the Human Body, for the Use of Students of Anatomy and Nurses. By LOUIS BATHE RAWLING, F.R.C.S. Eng., Assistant Surgeon and Senior Demonstrator of Anatomy, St. Bartholomew's Hospital. With four figures and explanations. London: The Scientific

Press, Limited. 1905. Price 3s. 6d. net.—This is an inexpensive and useful atlas by the aid of which a good knowledge of the muscular elements which enter into the formation of the contour of the human body can be rapidly attained. The positions of the motor nerve trunks are also indicated. We should like to see the book in the hands of all medical students and nurses.

The New Hygiene: Three Lectures on the Prevention of Infectious Diseases. By ELIE METCHNIKOFF. With a preface by E. RAY LANKESTER. London: William Heinemann. 1906. Pp. 104. Price 2s. 6d.—In this little volume we have a translation of the Harben Lectures which were delivered in French by M. Metchnikoff in May, 1905. The author is, of course, well known as an eminent biologist who has for many years been connected with the Pasteur Institute in Paris. For the subjects of the three discourses addressed to his London audience he selected the Hygiene of the Tissues, the Hygiene of the Alimentary Canal, and Hygienic Measures against Syphilis. In the first lecture he dealt mainly with the influence of phagocytosis in producing immunity against microbial infection, the existence of pathogenic bacteria in healthy persons, the formation of agglutinins and sensitising substances in the blood serum of patients, Sir A. E. Wright's discovery of opsonins, and the action of alcohol in weakening the natural power of resistance to infection. In the second lecture he suggested that appendicitis and some other diseases might be due to inoculation of microbes on punctures of the lining membrane of the bowel by intestinal worms. In the third lecture he recommended mercurial inunction as a protective against syphilitic infection. The literary form of the lectures is excellent and this brief summary is sufficient to show that the subjects dealt with are of great interest and importance. The translation is, on the whole, very readable; on pp. 6 and 8, however, a quaint effect is produced by the two adjectives typhoid and enteric, as applied to fever, being sometimes used in the same paragraph.

Hygiene of the Nursery. By LOUIS STARR, M.D. Seventh edition, with 25 illustrations. London: H. K. Lewis. 1906. Pp. xii.-309. Crown 8vo. Price 3s. 6d.—In the preparation of this edition the subject matter has been carefully revised and amended wherever necessary to keep abreast with the advances and improvements made in the methods of managing infants and children. Special attention has been given to the chapter on Food and numerous additions have been made to the Dietary and to the section devoted to Emergencies. The chapter which deals with the choice of a nurse-maid and the qualifications to be sought for may be read with benefit by every mother. The author sets forth a series of hygienic rules which can hardly fail to maintain the nursing in good health, to give vigour to his frame, and to lessen the susceptibility to disease. Little reference is made in the volume to drugs or methods of medical treatment, the author's object being to show a mother how she can keep her baby well by using preventive means. The first chapter is written with the object of hinting to the mother when she may expect the onset of disease and should call in professional counsel. We think that this edition will meet with the favour which the public has accorded to its predecessors.

First-Aid Tablets of Fractures. By S. O. EADES, L.R.C.P. Edin. Ipswich: W. E. Harrison. Pp. 45.—The author of this little book reminds us that from a beginner's point of view scientific facts may be divided into those which are seen and daily met with by the student, and which he readily masters, and those which he studies and endeavours to remember, with no inconsiderable trouble, but unfortunately easily forgets. This book is intended for the latter class. The object of the author is threefold: (1) to help those who are studying for first aid and for competitions; (2) to recall to

memory at a glance facts easily learnt and as easily forgotten by first-aid certificate, voucher, medallion, and label holders; and (3) lastly, to encourage the good work which is being carried out by members of the St. John Ambulance Association and Brigade. The little book is written in a practical way and clearly points out what should and what should not be attempted by those who practise first aid. It will be helpful to those for whom it is intended.

From Her to Him. By GEORGE H. R. DABBS, M.D. Aberdeen: Charles William Deacon and Co. 1906. Pp. 65. Price 2s. 6d.—In this poem, which is dedicated "To the Memory of a Noble Woman," Dr. Dabbs tells a pathetic story in suitable language and setting, the pathos at times almost amounting to pain. The work affords glimpses into the environment of a beautiful life.

The Tourist's India. By EUSTACE REYNOLDS-BALL, F.R.G.S. London: Swan Sonnenschein and Co., Limited. 1907. Pp. 364. Price 10s. 6d.—Mr. Reynolds-Ball is the guardian angel of the tourist. He is always ready to hold out a helping hand to anyone who wants to "do" the Mediterranean in six weeks or India in three months. To do him justice, however, he seems to be under no delusion as to the objectionable qualities of the cold weather tourist, and in Chapter II., which, however, is written by a friend of Mr. Reynolds-Ball, is quoted a remark of Mr. Hope Moncreiff about "T.G.'s" which is altogether illuminating. The tourist, however, will find a great deal of information in Mr. Reynolds-Ball's book, also some excellent photographic illustrations. We cordially agree with him when he says (p. 322) that alcohol should not be consumed as a beverage in the tropics, though, of course, it must be remembered that a large portion of India is anything but tropical. We must, however, join issue with him on some of his medical instructions. In THE LANCET of Jan. 31st, 1903, we reviewed his book on travelling in the Near East and pointed out errors in some medical instructions. He has reproduced these errors in the work before us in all their inaccuracy. For instance, he talks about washing out the wounds caused by the bites of wild animals with an antiseptic, but, as before, gives no details as to how this is to be effected; and, worst of all, he reproduces exactly the following absolutely useless receipt for an improvised stretcher, or hammock as he prefers to call it. "A hammock can be improvised by running a stick through the sleeves of a great coat or ulster." This piece of information is no good to anyone. In the review quoted above we explained how he should have described the coat stretcher, and we again draw his attention to it. Should the work reach a second edition an index should be provided, and the present edition is so carelessly bound that we feel sure that the book would be in pieces before it had been used for a week.

THE MULKOWAL DISASTER.¹

It will be remembered that inoculation on a vast scale was undertaken in the Punjab in the winter of 1902-03 with Haffkine's anti-plague prophylactic. Over half a million people were operated on in the plague season of that year and of this number about a quarter were inoculated with prophylactic prepared by agar cultivation and sterilised by heat, and the rest with material cultivated in broth and aseptically by the addition of a small quantity of carbolic acid. From a report issued by the Government of the Punjab in 1904² it appears that the result of the measure was to reduce the liability to attacks among the inoculated to about one-fourth of what it was among the non-inoculated people and the liability to death from plague to nearly one-twelfth; and it is estimated that the number of lives saved amounted to at least 10,000. A deplorable accident, however, attended this campaign. On Nov. 4th and 5th,

¹ Supplement to the Gazette of India, Dec. 1st, 1906.

² Report on Plague and Inoculation in the Punjab from Oct. 1st, 1902 to Sept. 30th, 1903, by Major E. Wilkinson, I.M.S., chief plague medical officer, Lahore, 1904.

1902, 19 persons who had been inoculated on Oct. 30th from a bottle of agar prophylactic in a village called Mulkowal, developed tetanus and succumbed to it between Nov. 6th and 9th. The matter was investigated by a commission in India and was subsequently submitted for examination to the Lister Institute. On Dec. 1st, 1906, the Government of India issued in Calcutta, in the form of a supplement to the *Gazette of India*, a file of documents referring to the subject. We submit the essential points of the inquiry as gathered from these documents, and our readers will at once perceive the importance of the questions involved.

The following appear to us to be the main facts. The 19 people were inoculated, by means of the same syringe, with prophylactic from a bottle which was one of five filled from one and the same laboratory cultivation flask. The cultivation was marked "53 N." The four other bottles were used for inoculation elsewhere and caused no ill effects; the syringe before being refilled for another batch of inoculations was rinsed out with carbolic lotion.

The people who developed tetanus were the first of a batch of about a hundred inoculated in Mulkowal on that morning. They were the only persons inoculated from bottle 53 N. and none of those inoculated after them from other bottles had any untoward symptoms. The accident was therefore closely connected with the bottle used and the particular syringe with which the contents of that bottle were injected, and the question presented itself as to whether that bottle was contaminated at the time of using it in Mulkowal or at the time of its preparation in Bombay and what were the circumstances in which contamination occurred. An interval of several weeks separated the possible dates of contamination, for the bottle was prepared 41 days, and despatched to the Punjab 26 days, before the accident.

The possibility of getting an answer to the primary question lay in the fact that a tetanus impurity falling into a bottle of agar prophylactic does not remain dormant but starts growing. The Indian Commission and the Lister Institute ascertained that in a few days a rich culture of tetanus develops in that medium. The culture gets extremely active and when the Mulkowal germ was used for the experiment the culture gave tetanus to guinea-pigs in doses of $\frac{1}{1000}$ th and $\frac{1}{10000}$ th of a cubic centimetre. (With a culture made in ordinary media $\frac{1}{100}$ th of a cubic centimetre was required to cause such an effect.) The fluid acquires also an unmistakable disagreeable odour, as happens with most anaerobic fermentations and putrefactions. Such a rich culture develops, however, only when the germ is left in a bottle full, or practically full, of prophylactic, the tetanus bacillus being an anaerobe. When left in the remnants of fluid, in a bottle emptied of its contents, the air present in the bottle inhibits the growth of the tetanus bacillus. This, however, is only the case when the bacillus is introduced by itself, free from admixture of other microbes. If aerobic germs gain access to the bottle at the same time, the tetanus microbe develops even in a few drops of fluid, but only in proportion as the other microbes present absorb the air dissolved in the fluid. In the two eventualities—i.e., (1) in the case of a contamination occurring at the time of opening a bottle for use, on the one hand; and (2) in the case of contamination at the time of preparing it, several weeks previously, in the laboratory—the condition of the contents of the bottle will, therefore, be very different. In the first case the bottle will contain only a relatively insignificant amount of impurity, such as is met with in natural or surgical tetanus accidents; in the other, it will present, so to say, a solid mass of tetanus and toxin, and the men inoculated will get an amount of virus such as in no circumstances occurs in natural accidents.

On the question as to whether an insignificant amount of tetanus, dropped into and diluted in a bottle of prophylactic at the time of using it, can affect 19 individuals, several experiments were made by the investigators and are published in the supplement. In one experiment a minute bit of straw contaminated with tetanus was introduced into a prophylactic bottle. A sixtieth portion of the contents of the bottle was then examined; a culture inseminated from that portion revealed tetanus bacilli. In another experiment a syringe needle dipped into a culture of tetanus was allowed to dry, and was then used for ejecting 20 cubic centimetres of a sterile fluid, in doses of one cubic centimetre each. The fluid conveyed tetanus germs up to the seventeenth ejection, the eighteenth and nineteenth were not examined;

in the twentieth no tetanus was found. In another experiment a bottleful of prophylactic was contaminated with one platinum loop of a fluid tetanus culture, and was then injected at once into guinea-pigs, with a thirtieth portion of the prophylactic each. Every animal contracted tetanus.

The possibility of 19 inoculations conveying tetanus germs from an accidental impurity falling into a bottle at the time of inoculation must therefore be considered as established. If the subjects of inoculation at Mulkowal were inoculated with such an accidental impurity the course of the disease exhibited by them should, on the whole, correspond in rapidity of onset and development of symptoms to what has been usually observed in India in cases of tetanus where the infection has been contracted in the usual way. On the other hand, if a rich culture of bacilli and a mass of manufactured toxin had accumulated in the bottle before the time of using it we should expect a much more rapid onset of symptoms. The character of the disease in the Mulkowal patients pointed to an average degree of gravity of infection and the symptoms were, in fact, slower to develop than has been observed to be the case in many accidental cases.

The bottle was carefully examined at the time of opening it for use; it had no smell of any kind and appeared normal in appearance and every other respect. The smell is a very valuable index of a tetanus growth having taken place in the fluid, and as it has been ascertained that this smell becomes unmistakable within three days of contamination the conclusion is justifiable that the prophylactic contained in bottle 53 N. had not been contaminated with the tetanus bacillus even for this short period.

Fifteen days after the inoculation the incriminated bottle was recovered and the remnants of fluid found in it were examined by Lieutenant-Colonel D. Semple, R.A.M.C. A mixture of a few tetanus bacilli presenting a "poor culture," and of a common microbe was found in it. The "poor culture" corresponded to one that would develop in the presence of air, in the few drops left in the bottle after it was emptied. With the culture thus developed the bottle acquired the characteristic smell. The effect on animals on which the fluid was tested was found to be several times weaker than that of a culture grown in a full bottle.

Lastly, the following fact bearing on the question was established by experiment. The Mulkowal operator worked with two syringes. After using up a bottle of prophylactic, he filled his syringe with carbolic lotion and left it for three or four minutes before using it again on another bottle, and operated in the meantime with his other syringe. It has been found that a syringe which had been filled with a rich culture of tetanus, such as develops in a full bottle of prophylactic, remained infective after such a process of cleaning and gave tetanus to 17 guinea-pigs out of 19, on which it was afterwards used. On the other hand, a syringe which had been in contact with a feeble culture of tetanus, or of which the needle alone had been so contaminated as to convey tetanus in 19 consecutive injections, was rendered safe after that process of cleaning. None of the subjects on whom the syringe was used in Mulkowal, subsequently to the cleaning applied after the first bottle was finished, suffered from tetanus. This indicates that that bottle did not contain the kind of culture which left the syringe infective after the summary cleaning.

The circumstances in which the inoculations were carried out at Mulkowal made accidental contamination possible. The operations were performed by Dr. A. M. Elliot in the open air on the outskirts of the village. Shortly before the commencement of the campaign a "plague manual" was issued to the inoculators. According to that manual "the opening of bottles of prophylactic and the filling of syringes are the chief duties of the compounder. If there is great press of work the duty of actually opening the bottles may be entrusted to any intelligent person, care being taken to see that he observes the above instructions carefully." The instructions in question prescribed as follows: "The compounder, in proceeding to open a bottle, must shake it well, then dip its neck in carbolic lotion, 1 in 20, and then, with a pair of dissecting forceps, which when not in use are to be kept in the carbolic lotion, remove the cork." At Mulkowal the cork was tightly fixed in the bottle and the compounder in withdrawing it dropped in the bottle and the compounder in withdrawing it dropped his forceps on the ground; he picked them up, hurriedly dipped them in carbolic lotion, and then completed the removal of the cork.

The above is a résumé of the facts set out in the voluminous supplement to the *Gazette of India*. The Commission

appointed to inquire into the case in India makes references to them, and the Lister Institute, to which body the technical portions of the report of the Indian Commission were referred, does the same. Mr. Haffkine's comments upon the findings of both bodies are published in the form of two letters addressed in the spring of 1906 to the Under Secretary of State for India. Our account is necessarily much abbreviated, but it seems to us that the supplement is unnecessarily lengthy.

Regarding the absence of smell in the bottle used at Mulkowal the Indian Commission says:—

No doubt the presence of tetanus, at any rate in a pure culture, may be detected by one experienced and on the alert by its characteristic smell; our personal observation, however, leads to the conclusion that all bottles of plague prophylactic have a peculiar and not agreeable smell, so that Dr. Elliot, under the circumstances under which he was working, may well have failed to specialise a tetanus smell.

Mr. Haffkine, commenting on their words, observes that in the above statement the detecting of the presence of a smell is confused with specifying a smell. It is the latter that requires an experienced person and it is also for specifying a smell that the culture requires to be pure—i.e., not adulterated by the smell from another fermentation. In the Mulkowal bottle it was established that there was no smell whatever, not that it had a smell the character of which was not specialised. To ascertain such a fact a specialist is not required. The statement of the Commission, he considers, confuses the broth prophylactic, which has a slight smell of broth and carbolic acid, and which was not in use at that period of the campaign, with the agar prophylactic, with which Dr. Elliot, the operator, was working and which is free from any smell. Dr. Elliot, who had been on inoculation duty for two years before, stated on evidence that he was perfectly familiar with that difference. His sense of smell was tested before the Commission and bottles of the two varieties of prophylactic were placed before him without his being told which they were. He distinguished without hesitation the two kinds of bottles and rejected at once the Mulkowal bottle, which was mixed up with the others, as being unfit for use.

The Lister Institute refers to the question of smell as follows:—

That a bottle presumably tightly corked (vide Dr. Elliot's evidence) should contain enough tetanus growth to destroy 19 people, and yet not be accompanied by sufficient smell to arouse the suspicion of Dr. Elliot, who, according to his evidence, remembers smelling this particular bottle, is difficult to comprehend.

From a subsequent explanation given by the institute, it appears that it did not consider the existence of a tetanus "growth" necessary in order that the bottle should contain enough germs to destroy 19 people; and the above pronouncement regarding the absence of smell was explained by it as meant to be in favour of the Bombay Laboratory.

Regarding the similarity of the disease developed in the Mulkowal patients with that observed in accidental cases of tetanus, the Indian Commission says:—

It must be conceded that in experiments on animals the rapidity of the onset is influenced by the amount and virulence of the toxin introduced, and a priori we see no reason for saying that similar results might not follow the injection of the tetanus microbe with its toxin into the human body. Manifestly there can be no appeal to clinical experience which is based on observations of cases where it must be supposed the microbe alone has been introduced and symptoms—after it has established itself in the injured part. Though India is a period which substantially corresponds with what was manifested at Mulkowal, it is impossible to say, in the absence of experiment, what the sequel would be where a ready formed toxin is injected into the human system.

Mr. Haffkine points out that while in all other instances the Commission based conclusions on the result of animal experiment, the above is the only instance in which it did not apply to man a rule which should have no exception, whatever susceptible animal or whatever disease be in question—viz., that a dose of ready manufactured toxin hastens the incubation of a disease and the development of a fatal issue.

Referring to the facility with which the syringe in Mulkowal was freed from tetanus, the Indian Commission quotes experiments (Nos. 1 and 2, Appendix B of the Report) in which Lieutenant-Colonel Semple found that when he filled a syringe from a tetanus culture developed in a emptied and cleansed it in the way done at Mulkowal, it still retained enough tetanus to infect 17 out of 19 animals on which it was afterwards used; while when a

feeble growth of tetanus was substituted for the above the syringe, after cleansing, appeared harmless. It says: "There are no means of forming an opinion as to the precise richness of growth in Bottle 53 N. beyond Lieutenant-Colonel Semple's view that it was a poor growth in comparison with that which he used in his experiments Nos. 1 and 2 in Appendix B. This view is based on (1) microscopical specimens, and (2) the rapidity of the fatal effects on guinea-pigs."

The Lister Institute on its part remarks:—

Whether the inoculation of a fluid containing tetanus organisms into the body of an animal is or is not followed by the disease, depends, as was shown by Semple, upon the number of organisms introduced under the particular circumstances.

Mr. Haffkine points out that, had the Mulkowal bottle been contaminated in Bombay and tetanus developed in it while it was full of prophylactic, it would have been just in the condition of the bottle which Lieutenant-Colonel Semple prepared for his experiments Nos. 1 and 2, and which left the syringe contaminated after cleansing; it would not have been in the condition in which Bottle 53 N. was when seen by him. The absence of untoward symptoms in those inoculated with the Mulkowal syringe after the first 19 persons confirms, therefore, the fact that the bottle used did not harbour tetanus cultivated since the preparation of the prophylactic in Bombay. There is also no ground for saying that Bottle 53 N., when seen by Lieutenant-Colonel Semple 15 days after the accident, was in the same condition as at the time of inoculation; everything, on the contrary, indicates that the "poor growth" seen by Lieutenant-Colonel Semple developed in the remnants of the fluid subsequently to the bottle being emptied.

The conclusion of the Indian Commission.—The ultimate conclusion of the Indian Commission upon the question of the place of contamination was as follows. Against the considerations favouring the view that contamination was introduced at Mulkowal "there is," it says, "the fact that the specific contamination permeated the whole fluid in the bottle, as is shown by the uniform results of the sufferers; and without a series of suppositions opposed to all reasonable probability these results can only be attributed to a growth of some duration, though not necessarily of great vigour." On account of this it concludes that the contamination had entered the bottle in Bombay at one of the stages of the laboratory preparation.

The conclusions of the Lister Institute.—The Lister Institute gave its conclusion on three occasions. First, in a detailed report in November, 1904, and comprising the description of all the experiments made by it. In this report the institute expressed the opinion that contamination was most probably at the time of inoculation present in the fluid, but that it was impossible to determine when it had entered it. This conclusion was referred to as being the same as that come to by the Indian Commission. The second pronouncement, communicated to the Under Secretary of State for India on Nov. 9th, 1905, was in the following letter from the director:—

In reply to your letter of 2nd Nov., 1905 (R. & S. 2555) I am directed to state that the institute is of opinion that the fluid used at Mulkowal probably became contaminated with tetanus before the time of opening the bottle at Mulkowal, but it also agrees with the Commission (extracts from the report of the Punjab Plague Inoculation Commission, page 5, sixth line) that the possibility of the contamination having effected an entrance at Mulkowal cannot be excluded.

Lastly, in May, 1906, the following report was given:—

In further reference to your letter R. & S. 502, of the 9th March, 1906, I have now the honour, by direction of the governing body of the Lister Institute, to submit to you the following observations on the letters from Mr. Haffkine of the 14th February, 1906, and the opinion that the probabilities were in favour of the view that the tetanus impurity was primarily in the fluid, did not feel justified in asserting this as a proved fact in view of the possibility of contamination at Mulkowal. The governing body regret that in their report of the 24th Nov., 1904, they inadvertently referred to their conclusion as the same as that of the Commission. The sentence in the Government Report that gave rise to this idea was, "That if (the contamination) might have effected an entrance at Mulkowal cannot be disputed; thus, by way of illustration, the stopper or the forceps might have been dropped on the ground and applied to the mouth of the bottle with contamination adhering, or spores settled between the rubber stopper and the rim of the bottle might have dropped in as the stopper was pulled out." The governing body overlooked the fact that the Commission subsequently considered this possibility as one cancelled by other considerations. But in this respect the governing body are bound to say they cannot fully concur, and while holding to their view of the probability, they think Mr. Haffkine has a right to claim the benefit of the doubt, especially in view of the fact elicited that the forceps used for drawing the cork at

Mulkowal were dropped on the ground and subsequently re-used by the operator on the same cork.

The governing body also regret that in the first paragraph of the section of their report dealing with the probable origin of the tetanus virus (page 3), to which Mr. Haffkine draws attention in his letter of 14th February (page 31), the words "the fact" were drafted into the sentence. The words should have been omitted and the sentence should have run: "But that a bottle, presumably tightly corked, should contain enough tetanus growth to destroy 19 people, and yet not be accompanied by sufficient smell to arouse the suspicion of Dr. Elliot, who, according to his evidence, remembers smelling this particular bottle, is difficult to comprehend." Mr. Haffkine is certainly entitled to this correction, though the argument in his favour was already clear from the context.

Mr. Haffkine points out that, with reference to the circumstances in which the inoculations were carried out at Mulkowal, it is known that it takes some 15 hours to destroy a tetanus impurity by carbolic lotion. The procedure prescribed could not asepticise the mouth of a bottle on which such an impurity might have settled in the open air, or sterilise a pair of forceps contaminated by being dropped on the ground. It appears that these instructions were prescribed in substitution of those issued by the laboratory, and which directed that "dissecting forceps are to be used for removing the stopper. The branches of the forceps are heated in the flame of a spirit lamp immediately before use and guarded from contact with any unsterilised object afterwards." The stopper and neck of the bottle are then passed several times through the flame of a lamp so as to cause very slight singeing of the stopper, and the latter is withdrawn with the heated forceps. After the bottle is opened any contact between its mouth and other unsterilised objects is to be carefully avoided, and if contact inadvertently occurs, the mouth of the bottle is to be heated again in the flame to disinfect it."

Lastly, we must briefly refer to the modifications of Haffkine's prophylactic, as questions arising here were dealt with in the course of the Indian Inquiry. It seems to us a pity that the inquiry was not kept strictly, at any rate in the first instance, to the all-important point of the time of the contamination of the deadly fluid. It has been mentioned in the beginning of this note that the prophylactic used in the Punjab was prepared partly from agar cultivations sterilised by heat and partly from broth cultures to which a small proportion of carbolic acid was added. Either of these processes is in use in European and American laboratories. The agar method of preparing the prophylactic with sterilisation by heat has been in use in the Pasteur Institute in Paris since 1900. Many of the antitoxic sera are sterilised by heat but in some laboratories a small proportion of antiseptic is added to them. That the addition is not without benefit no one denies but too much must not be claimed for it. For instance, the accident which occurred in Italy in 1900, and which involved the death of some 20 people from tetanus, was caused by the injection of an antidipteric serum prepared with 0.5 per cent. of carbolic acid.

The above considerations as a whole, facts and comments and theories, point, in our opinion, strongly to the conclusion that the laboratory was not at fault. We congratulate the Government of India upon publishing the supplement even after the expiration of a considerable interval of time. The value of preventive inoculation is as yet barely recognised by the public and apprehensions that errors in laboratory procedure may lead to appalling disasters will be for some time strong. It is a distinct advantage to the cause of scientific therapeutics that good reasons should be made publicly known for attributing the Mulkowal disaster to an accident at the periphery of the scheme and not to a central blunder.

Another point cannot be ignored. For four years Mr. Haffkine, the director of the laboratory in which Bottle 53 N. was prepared, has borne in the minds of many responsibility for the disaster, and justice required that the Government of India should make known to the public the degree of responsibility of its distinguished servant. We do not know what reasons the Government may have had for the slow course pursued, but the advantage which arises therefrom—one which we do not expect Mr. Haffkine to appreciate—is that the matter can be discussed with a freedom from personal bias that would have been impossible at the date of the disaster. The matter is over; what is necessary is that the experience gained from an investigation of the facts should be used to the full in the interest of the developments of scientific medicine.

Looking Back.

FROM—

THE LANCET, SATURDAY, Jan. 31st, 1829.

SURGICAL REFORM DINNER TO MR. WAKLEY.

Mr. Paty to Mr. Wakley.

33, Bouverie-street, Fleet-street,
Jan. 24th, 1829.

DEAR SIR,—The gentlemen who undertook the arrangements connected with the resolutions, adopted at a public meeting in the Freemasons' Tavern, on Tuesday, Dec. 23rd, 1828, (a copy of those resolutions having already been transmitted to you,) have requested me, as Chairman of that meeting, to inform you, that, should the day suit your convenience, they consider the 18th of February next, the most proper time to beg the favour of your company in the same tavern, at a public dinner.

I beg leave to state also, that their reason for naming that day in preference to any other, was, that it will be the anniversary of the commencement of those proceedings which, if zealously pursued, with the continued assistance of a Free Medical Press, will tend to raise your professional brethren from their present degraded condition; which has been attributed, with justice, to the constitution and government of the Royal College of Surgeons in London.

An answer to this letter, at your earliest leisure, will oblige the gentlemen at whose request I write; and also,

Your most obedient Servant,

Thomas Wakley, Esq.

JAMES PATY.

Mr. Wakley to Mr. Paty.

Bedford-square, Jan. 24, 1829.

DEAR SIR,—I need scarcely say, that I feel most sensibly the very flattering testimony of approbation, which my public conduct received from the large and respectable meeting, over which you presided on the 23rd of December, at the Freemasons' Tavern. My exertions in the cause of a Free Medical Press, and Free Medical Institutions, have, at least, been honest, and honest exertions the public of this country never fail to appreciate. I am sensible also, that the late trial has contributed greatly to strengthen the hands of public writers, by the important decision given at the outset of the cause, in favour of Journalists who feel that they are in a situation to justify an alleged libel, and also to open the eyes of the public to the corrupt system which prevails at our hospitals in the distribution of patronage, though I was not permitted to enter fully into this part of the case. But, Sir, greatly as I deprecate and detest the system of nepotism, to which, I believe, Mr. B. Cooper is indebted for his situation, I entertain, equally with yourself, and the gentlemen whom you represent, no kind of hostility towards that gentleman. On the contrary, I respect his private character, and I would rather not, therefore, at present attend a festival, which, though instituted entirely upon public grounds, malevolence might perhaps construe into an act of persecution directed against his private interests. If the object of the festival were to celebrate the triumph of surgical reform, I should be proud and happy to attend. But though the victory is, I believe, in our hands, the battle is still to be fought. I trust, however, the day is not far distant when we may meet to celebrate, not the virtual defeat of a few individuals, but the complete and final overthrow of a corrupt system.

In conclusion, permit me to express my deep sense of gratitude towards yourself, and the gentlemen with whom you are acting, for your very flattering and distinguished approval of my efforts in the noble and thriving cause of Surgical Reform.

Your obliged and obedient Servant,

James Paty, Esq.

THOMAS WAKLEY.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 2, 1907.

The Harvest of the Sea.

PROBLEMS connected with the harvest of the sea must necessarily attract the attention of all those interested in the world's food-supply. HUXLEY once said that the productivity of the sea was so great that man's influence on its wealth was scarcely worthy of regard by comparison; and yet the experience of the past 25 years has shown, at any rate for certain seas, and notably the North Sea, that man's influence is not by any means without serious effect. In the North Sea there has been an enormous development of trawl-fishing and there are statistics which distinctly indicate that the plaice, the haddock, the sole, and the turbot have diminished, not only in regard to total catch but in regard to size also. Concerning the sole and the turbot in particular an analysis has revealed an unmistakable decrease as regards the total quantities caught in the North Sea, while the quantities of the large fishes have continually decreased, and the quantities taken of the small have not sufficiently increased so as to maintain the total quantities at the same uniform level. There are, of course, a number of circumstances besides over-fishing which probably contribute to this result; there are the peculiar habits of the fishes themselves to be taken into account, there may be changed physical conditions or stresses of weather which have led the fishes to change their habitat, or it may be that the vast catches of undersized fishes are reducing the piscatorial productiveness of the sea. Whatever the real reason may be the fact that the harvest of certain fishes is year by year getting less bountiful is a serious outlook, especially for this country, and presents a problem which, bearing in mind the great importance of this auxiliary food-supply to the community, it is our duty to try to solve. It is interesting to recall also that a fish famine not many years ago seriously diminished the supply of cod-liver oil.

Common sense has taught us what is the result of neglecting to study the conditions of the land which are favourable to the cultivation of food-yielding plants and animals. Scientific methods are now available as a powerful aid indicating what should be done in order that where one blade of grass formerly grew two or more might be induced to grow by scientific treatment of the soil. If we have profited by utilising the experience and the results of scientific investigation as applied to increasing the productiveness of the soil, surely we may profit also by applying similar principles to the sea.

Fish occupies a very important and valuable place in our supplies of food and it is hardly reasonable to suppose that the enormous catches year by year can be taken without ultimately affecting the yield, at any rate in the immediate neighbourhood of our shores. It is, of course, hardly conceivable that the productivity of the whole world's ocean would be materially affected by the fishing operations, extensive though they may be, which are confined to the shores of the small islands which compose Great Britain. But it should be remembered that the fish-supply of this country is very largely dependant upon the success met with by our home fisheries, and this fact affords a sufficient reason why the study of the economy of the sea should be pursued vigorously in this country and the knowledge so gained applied without loss of time. We do not forget, however, that this study has already been well begun and with the most encouraging prospects, but the organisation of inquiry has been so far on too small a scale and the scope of the investigation is enormously wide. Results of the most interesting and practically important kind have been gained for us by the admirably directed efforts of the Marine Biological Association of the United Kingdom, by the Lancashire and Western Sea Fishery Committee in association with the Liverpool Marine Biology Committee, and by the Irish and Scottish Fishery Boards, while fortunately we possess an Association of Economic Biologists, which held its fourth annual meeting at Cambridge a week or two ago and at which one at least important paper bearing upon the study of the economy of the sea was read and discussed. The British Government, however, offers very little practical encouragement to workers in the field of marine research. It possesses a Board of Agriculture, which is doubtless a source of some scientific help to farmers of the land but there is no department which is concerned in helping to maintain the harvest of the sea. There is no substantial Government aid offered which is calculated to promote the study of marine life and environment, to throw light on which may ultimately mean the preservation of one very important source of food-supply.

To do the Government justice, however, it was on the occasion of the formation of an international council at Copenhagen in 1902 for the study of the sea that it was decided to appoint British delegates who were instructed to report from time to time on the work of this international council. These delegates published their first report some time ago and it has recently been succeeded by a second contribution in the form of a Blue-book which amounts to a review of the organisation of the scientific and practical work of the international investigations, and of the methods, means, and results, in so far as these have assumed a definite character at the present time. We have nothing but admiration for the splendid organisation which has been formed and for the extraordinary tact with which each section of the investigation has been allotted to each special investigator. Amongst these it is pleasing to see the names of some well-known English authorities. In order to reap practical results as soon as possible it was decided to concentrate the biological investigation of the first years on certain practical and important problems, and the first objects of investigation were (1) the migrations of the

principal food fishes of the North Sea fisheries, especially of the cod and the herring; and (2) the question of over-fishing in waters mostly fished by British, Dutch, German, and other trawlers, with special regard for the plaice, sole, and other flat fish, as well as the haddock. Meantime the periodical and other variations of the Atlantic currents and their bearing on meteorological and biological phenomena have been studied, the marine organisms (the food of the fishes) have been taken at various stations and by trade steamers and investigated, the composition of the sea water in relation to its constituents which support marine algae has been brought to light, the occurrence and the distribution of the eggs and various age groups of the food fishes have been examined, fishes have been marked and caught again after a time and inspected, and so forth. Thus may we arrive at the determination of the questions as to how the fish nourishes itself, reproduces its kind, whether over-fishing is going on, whether a fish is stationary or migratory, whether an influx from one sea is occurring to compensate for the fishes removed from another, whether oceanic currents or changes of temperature have any bearing on migration, and other equally important questions, the answer to which must have results of far-reaching importance to the fishing industry and to the community generally. The whole scheme is aiming at exact knowledge and the progress so far made affords a fascinating study and is of a most instructive kind. The extraordinary migratory movements of the plankton, the organisms of the sea, promise to give the best clue as to the movements of their consumers. The rôle therefore played by the plankton in the economy of the sea is probably pre-eminent in importance in regard to the immediate object of the inquiry. The growth of plankton, it would appear, must be localised; in other words, food must be found and located for the fishes, just as the grasses, by the fertilisation of the soil, must be stimulated to bring forth abundantly in order that our sheep and cattle may thrive. "The production of plant substance in the sea," writes Professor BRANDT, "may be compared with that on land by arranging the chemical composition as to quality and quantity along parallel lines. We may determine how much organic substance in general and in particular how much albumin, fat, and carbohydrates are formed per unit of surface during the course of the year on the one hand for land (i.e., pasture), on the other hand for water. The two more closely studied main groups of plankton flora, the Peridineæ and the diatoms, are very nearly related in composition to the best forage, and in autumn the plankton of Kiel Bay has, in general, almost the same composition as pasture."

It is doubtful whether any previous scientific research has ever assumed the colossal proportions of this fisheries inquiry and certainly there never has been such a splendid example of the value of scientific international coöperation. An intensely interesting series of scientific experiments is being conducted by clever and skilled men representing all nations. The questions thus being so carefully studied are the concern of the whole world and the wish that success will crown these inquiries must be universal. The sea will then be fished on rational and not empirical lines and an unflinching and constant source of food-supply will, it is hoped, be the reward.

The Actions of Pituitary Extract.

A MOST fruitful field of investigation in physiological research has been opened out in recent years by the study of the interactions of the various organs of the body. On the one hand, it has enriched physiology by the elucidation of the so-called internal secretions and the more recently discovered group of hormones, while on the other hand it has yielded to medicine valuable information as to the pathology of certain obscure diseases and also therapeutic agents of proved value in thyroid extract, adrenalin, and other substances derived from glandular organs. A considerable amount of attention has been directed to the pituitary body in order to determine whether it forms some internal secretion and two views have been suggested as to its functions, one being that it produces a secretion analogous to that of the thyroid body and that it may act vicariously for that organ, and the other that it exerts some ill-defined influence upon the nutrition and growth of the extremities, especially of their bony framework.

An important paper has recently been communicated to the Royal Society by Professor E. A. SCHÄFER and Dr. P. T. HERRING¹ containing a record of some interesting experiments on the action of pituitary extracts upon the kidney. As the outcome of their research they suggest that the internal secretion of the infundibular portion of the pituitary body is ancillary to the functions of the renal organs. In 1901 Professor R. MAGNUS and Professor SCHÄFER² observed after injection of pituitary extract into the veins a marked increase in the flow of urine with expansion of the kidney—a remarkable result when the powerful vaso-constricting effect of the extract is taken into consideration, an effect only inferior to that produced by suprarenal extract. The objects of the research now under consideration were to investigate further this effect, to determine with which part of the pituitary body it was associated, and to study its relation to the substance raising the blood pressure. The extracts used were made almost entirely from the pituitary body of the ox, although in a few experiments extracts were made from the pituitary body of the dog and the cod with precisely similar results. According to Professor SCHÄFER and Dr. HERRING the pituitary body of the ox has the general shape and size of a large cob nut, and consists of two lobes, of which the posterior is the smaller and is imbedded in, and ensheathed by, the anterior, the relations of the two parts being thus somewhat similar to those of the cortex and medulla of the suprarenal body. There is a curved transverse cleft (the intraglandular cleft) separating the two lobes except near the circumference, which renders it an easy matter to shell out the posterior lobe and to obtain it separately when it is found to be relatively small, weighing only a few grains. It was shown by HOWELL that the substance acting upon the heart and blood-vessels is confined to the posterior lobe, and this is demonstrated to be true as regards the diuretic effect of the extract by the present research. As pointed out by the writers in their paper, this is the more remarkable because the anterior lobe presents an obvious glandular structure, consisting of masses of

¹ Philosophical Transactions of the Royal Society of London, Series B, vol. cxcix., pp. 1-23, 1906.
² Proceedings of the Physiological Society in Journal of Physiology, vol. xxvii., p. 9.

epithelial cells which in places surround a lumen or line a cyst-like cavity, while the posterior lobe is composed mainly of a tissue which resembles the grey matter of the nervous system containing many glia cells and, perhaps, a few nerve fibres and nerve cells. The extract used was prepared from the posterior lobes of a number of glands dried at the atmospheric temperature. The dried substance so obtained appears to retain its active properties for months or even years, and for use one part of the dried material was boiled with 100 parts of Ringer's solution and filtered. This extract is referred to as the 1 per cent. aqueous solution. Previous extraction of the dried material with alcohol or ether does not seem to diminish the activity of the saline extract prepared as above described.

The effect of the injection of such an extract upon the heart and blood-vessels, producing a general constriction of the arterioles with a marked rise of blood pressure, was shown by OLIVER and SCHÄFER³ and confirmed later by HOWELL,⁴ who also showed that the rise of blood pressure occurs in spite of a marked cardiac inhibition which may also be produced. He further observed the peculiar fact that a first dose of any magnitude confers an immunity as regards any effect on the heart or blood-vessels to a second dose given within 30 to 60 minutes; indeed, it was subsequently shown by SCHÄFER and SWALE VINCENT that a fall of blood pressure may be produced by second and subsequent injections and that the rise of pressure produced by the first injection may in some cases be preceded by a slight fall. The explanation offered by the last-mentioned observers was that the pituitary extract contained two substances having opposite effects (pressor and depressor), the former overcoming the latter usually in the first injection, while with subsequent ones a reversal is obtained. There are, as can readily be seen, certain resemblances in the action of pituitary extract to that of suprarenal extract, but they are certainly not identical, since the vascular contraction and cardiac inhibition obtained with pituitary extract are much more prolonged than those with suprarenal extract; moreover, the immunity to a repeated dose occurs only with the pituitary substance. Again, suprarenal extract acts as a general excitant of all glandular and muscular tissues that are innervated by the sympathetic system, which is not the case with pituitary substance. The most striking difference is, however, in relation to their effects on the kidney; for while suprarenal extract produces a marked constriction of the renal vessels and cessation of the flow of urine, pituitary extract produces dilatation of the vessels of the kidney and an increase in urine, sometimes preceded by a temporary diminution or cessation with or without a temporary shrinkage of the volume of the kidney. That this increase in urinary flow is not at any rate altogether due to the rise of blood pressure is proved by the fact that with second and subsequent injections the diuretic effect is still marked, although there is usually a fall of blood pressure—in other words, the immunity to second injections noticed with regard to the pressor and cardio-inhibitory effects of the extract does not extend to its diuretic action, which would seem also to suggest that it is due to a separate chemical substance. Another peculiarity is that the increased flow of urine is prolonged,

lasting long after the general vascular influence of the extract has passed off, while an interesting fact noticed in some animals is the prolonged period of latency which sometimes intervenes between the injection and the diuretic effect, which may extend to several minutes. It is also stated that the effect upon the kidney is not proportional to the amount given; indeed, within certain limits the kidneys seem to respond more readily to a small than to a large dose of the extract, a fact which the writers suggest is in consonance with the view that the pituitary body produces a secretion which is discharged into the blood and subserves a diuretic function. The effects of hypodermic injection and of injection of the substance into the stomach yielded somewhat indefinite results. On treatment of the pituitary substance with hydrogen peroxide it appeared that the substance acting on the blood pressure was rendered inert, while the diuretic substance was not affected. Reducing agents, on the other hand, apparently have no influence on any of the active constituents of the extract. The extract was not found to exert a similar action upon glands other than the kidney, its activity in promoting secretion being apparently confined to that organ. Professor SCHÄFER and Dr. HERRING conclude that the diuretic activity of this substance is far greater than that of any substance in the pharmacopœia, and since by its actions on the vascular system it tends to produce an optimum condition for renal activity and apparently in addition to exert a specific stimulation upon the renal epithelium, it is regarded as probable that its chief purpose is ancillary to the function of the kidneys. They further draw attention to the similarity in development, structure, and functions between the suprarenal and the pituitary bodies. Both occur in all vertebrates and each consists of two parts, one being a highly vascular epithelium and the other being of neuro-ectodermic origin; in neither are extracts from the epithelial and more obviously glandular portions active, whereas the neuro-ectodermic parts yield powerful substances. It is suggested that in both organs the active substance passes through certain stages of its formation in the epithelial part and is altered to its active condition in the neuro-ectodermic part.

These interesting and important researches are obviously of great practical importance and deserve careful consideration at the hands of clinicians and pathologists, for, as the writers suggest, it will be of interest to know whether diabetes, and especially diabetes insipidus, is associated with hypertrophy of the pituitary body. Moreover, the substance may prove to have a field of therapeutic usefulness.

Reminiscences of the Liverpool Lock Hospital.

IN the January number of the *Liverpool Medico-Chirurgical Journal* Mr. FREDERICK W. LOWNDES has given an interesting account of the Liverpool Lock Hospital and he has described the large amount of work which was there done. Soon after the first Liverpool Infirmary was opened in 1749 some 75 beds were set apart for the treatment of venereal disease. When the second Liverpool Infirmary was built in 1824 it was found that the demands on the available space were so great that there was no room in it for venereal cases. The need for accommodation for these cases was

³ *Journal of Physiology*, 1896, vol. xxiii.
⁴ *Journal of Experimental Medicine*, 1893, vol. iii.

met by the opening of the Liverpool Lock Hospital in 1834. In the venereal wards of the infirmaries and in the Lock Hospital much good was done not only for the patients but for our knowledge of venereal disease. Even in the early days of the Liverpool Lock Hospital the idea still existed that gonorrhœa and syphilis were identical, and it can hardly be doubted that the chief factor in the persistence of this opinion was the experiment in which JOHN HUNTER in 1767 inoculated himself with gonorrhœal pus and yet suffered from all the manifestations of syphilis. We now know that there was some error in the conditions of the experiment; probably the patient from whom the gonorrhœal pus was taken was also affected with syphilis. It took some years of observation to disprove this supposed identity and until this was done gonorrhœal cases were regularly salivated but in vain. When gonorrhœa had been definitely separated from syphilis there still remained the confusion of the hard and the soft chancre, and the confusion was very excusable, for occasionally the two poisons are inoculated on the same spot at the same moment and so the two sores are combined. It is easy for us with our present knowledge to recognise how the two may usually be distinguished but it must have been exceedingly difficult for those who worked at the subject to arrive at the truth.

Mr. LOWNDES studied at Liverpool from 1860 to 1863 and then he went to Edinburgh. At Liverpool he had seen the beneficial results of the careful administration of mercury. At Edinburgh he heard Professor HUGHES BENNETT who taught that mercury was useless in syphilis and should not be given. In opposition to this opinion Dr. THOMAS EDWARD BEATTY maintained that infantile syphilis and syphilis in married women were almost all due to lack of mercurial treatment of the husband, and with this opinion Mr. LOWNDES agrees. In 1875 he was elected surgeon to the Liverpool Lock Hospital and his experience since that time has only served to deepen his sense of the value of mercury in syphilis. He sees no need, and in this we agree with him, for patients to go to Aix-la-Chapelle for the treatment of syphilis as they can be perfectly treated in this country. When, however, a patient will not devote himself to his treatment but allows business or pleasure to interfere with it, then the regular habits at Aix-la-Chapelle, freedom from worry, and thorough treatment which cannot well be avoided, will often effect a cure which might otherwise have failed of accomplishment. With the year 1898 Mr. LOWNDES's active work at the Liverpool Lock Hospital came to an end and he was appointed consulting surgeon and at the same time the reception of in-patients ceased. It is a curious result of the modern spirit that the number of beds for venereal cases in this country is steadily getting less, though there is no visible decrease in the number of cases; there is a feeling that to provide for the treatment of venereal cases is to encourage vice. No attention is paid to the fact that many cases of syphilis occur in those who do not owe it to any vicious act. To allow syphilis and other venereal diseases to go unchecked because the majority of the sufferers from these diseases have transgressed is very unwise. The health of the nation as a whole suffers. As medical men we must not look to the manner in which a disease may have been contracted; we have to treat the diseased condition. As well might a physician refuse to

treat a patient with cirrhosis of the liver because the man's own self-indulgence had caused his sickness. It is often possible at the same time to add a "word in season" that may prevent a recurrence of the vice through which the disease arose but to diminish the amount of disease in the community is our main duty. The more thorough treatment of syphilis and other venereal diseases would go far to diminish the deterioration from which certain sections of the nation suffer and need in no way lead to the increase of vice.

Annotations.

"No quid nimis."

COOKING BY GAS: IS IT INJURIOUS TO THE MEAT?

THERE are some people who state that they can easily tell whether meat has been cooked by gas. They not only can see differences in the appearance of the meat but can also discern a peculiar taste for which the products of combustion of gas are in their opinion accountable. Cooking by gas by the method which is nearest to that known as roasting in front of the coal fire is generally conducted so that the meat is exposed to the direct heat of the gas flames, and the products of combustion sweep the surface of the joint. The gas-cooker is, in fact, merely a closed chamber or oven provided with a suitable number of gas-burners. An exit is commonly provided in order to allow for the escape of these products and hot air is necessarily circulated through the gas oven. If the cooking were done by the gas oven being heated on the outside it is difficult to see why such a process should be different in any respect from that in which the cooking is done in the ordinary range oven heated by a coal fire. The question narrows down, therefore, to a consideration of the effects which the products of gas combustion, whether they be complete or incomplete, are likely to have upon the meat. We may thus count upon the exposure of the meat to small quantities of such incomplete products of combustion as carbon-monoxide, acetylene, and sulphurous acid, and to the complete products carbon-dioxide, steam, and traces of sulphuric acid. It is well known that during the cooking of meat by whatsoever process the meat loses weight or, in other words, there is a constant emission of vapour, and consequently it can hardly be supposed that absorption can be going on at the same time. But assuming that not to be the case, what effects is the bombardment of small quantities of carbon-monoxide, acetylene, and sulphurous acid likely to have on meat and would these effects render the meat less suitable for food? Both carbon-monoxide and acetylene form molecular combinations with the colouring matter of the blood, but then at the high temperature of the cooking process it is hardly conceivable that such a combination could take place, besides which a plentiful supply of air would prevent either carbon-monoxide or acetylene from being permanently absorbed. The minute quantity of sulphurous acid would tend to bleach the colour of the meat, but as a rule no effect of this kind is observed. If sulphuric acid is formed this at a high temperature might possibly char slightly the surface of the joint. All such speculations, however, are strongly discounted by the fact that meat during its cooking is emissive and not absorptive. As to steam and carbonic acid, it is questionable whether they could have any depreciable chemical action at all. The conclusion seems inevitable, therefore, that any differences that are shown between meat cooked in front of the fire or

in an oven next to the fire and meat cooked in a chamber containing gas flames inside must be due entirely to physical and not to chemical causes. In a word, the explanation must lie in the different manner in which the heat is applied in the different circumstances. It should be borne in mind, however, that in cooking by gas the meat is exposed to a rapid current of steam derived from the combustion of the gas, whereas in the range oven the only steam present is that which comes from the meat itself, while in open roasting in front of the fire there is no atmosphere of steam round the joint at all, the air is free to play over its surface, and the cooking is done by radiated heat. We believe the process of open roasting is far superior to that of close roasting, the flavour of the meat so cooked is invariably better and the tissue itself is generally more tender when it is cooked by roasting, and, consequently, more digestible. We are inclined to put forward the view that the cooking of meat by gas is less satisfactory than cooking by the open roast method, because in the former case the joint is cooked partly by ascending heat currents and partly by steam. According to this view cooking by gas may be regarded as a hybrid process, that is to say, part boiling or steaming and part roasting. The constant stream of steam over the surface of a joint of meat is calculated to extract some of its flavour and to exert a toughening effect on the tissues of the meat. We do not think, however, that any difference between the effects of gas-cooking and cooking by roasting or in the range oven can be regarded in a serious light from a point of view of dietetics. The differences in our opinion are due entirely to different physical conditions under which the meat is cooked, and we may safely exonerate, we think, the gas-cooker from any suspicion of poisoning the meat by reason of the escape of unconsumed gaseous products from the gas flame. The process of grilling meat exposes that food to a torrent of incomplete products of combustion compared with what happens in the gas-cooker, and yet a grilled chop is very popular, "the taste of the grill" (the sulphurous acid and perhaps a little smoke) being held in esteem; but the gases round the chop in this case do not contain anything like the proportion of hot aqueous vapour which is present in the gas-cooker.

TYPHOID SPONDYLITIS WITH BONY CHANGES.

TYPHOID spondylitis is a rare sequel of typhoid fever which manifests itself during convalescence by painful stiffness, swelling, and tenderness of the lumbar spine. It appears to be due to serous inflammation of the periosteum and adjacent structures (perispondylitis). In the *American Journal of the Medical Sciences* for December, Professor Thomas McCrae of the Johns Hopkins University has shown that definite bony changes may result—a fact which does not appear to have been observed previously. He reports the following case. A man, aged 28 years, was admitted into hospital on July 4th, 1904, complaining of a stiff and painful spine. On Jan. 2nd he took to bed with a moderate attack of typhoid fever. Early in March, while convalescent, he awoke one night with severe pain in the back and had to lie flat because any attempt to rise caused acute pain in the lumbar region. Since that time his spine had been stiff. At the end of March he was able to sit in a chair and at the beginning of April he began to walk. During this time his back was stiff but not particularly painful except on movement of the lower part of the spine. His health gradually improved but the spinal condition grew worse and any exercise caused much pain. On admission there was almost constant pain in the lower part of the back and down the thighs. The patient was well nourished and his colour was good. The abdominal muscles resisted palpation. The spine was held perfectly straight and there was practically no
